In the asymmetric unit of the title compound, $\mathrm{C}_{10} \mathrm{H}_{15}{ }^{-}$ $\mathrm{N}_{4} \mathrm{O}_{2}{ }^{+} \cdot \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$, there are two protonated aminoguanidinium cations and two dihydrogenphosphate anions. The positive charge on the protonated amidine group is delocalized over the three $\mathrm{C}-\mathrm{N}$ bonds in a manner similar to that found in guanidinium salts. The aminoguanidinium cations are found to be the $E$-isomer structures. Intramolecular interactions of the $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ type are observed, leading to the formation of fivemembered rings. Extensive networks of $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}, \mathrm{N}-$ $\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds stabilize the threedimensional network. In the crystal structure, $\pi-\pi$ interactions between the benzene rings, with a distance of 3.778 (2) $\AA$ between the ring centroids, also affect the packing of the molecules.

## Comment

Aminoguanidine has been reported to be a potent inhibitor of nitric oxide synthase (Griffith \& Gross, 1996). Guanylhydrazones (alkenylaminoguanidines, carboximideamidehydrazones and diaminomethylene hydrazones) are condensation products of oxo compounds with aminoguanidines. This class of compounds has been known for some time (Thiele, 1892) and is of considerable interest due to the wide variety of different pharmacological activities found for many representatives (Richter et al., 1993; Schleuder et al., 1993). Furthermore, guanylhydrazones are valuable synthetic building blocks for ring-closure reactions, leading to several nitrogen-containing heterocycles (Sarıpınar et al., 2005). Protomeric tautomerism is of much interest in experimental as well as theoretical chemistry, since it is an important reaction in biological processes. Guanylhydrazones can exist in two tautomeric forms (Zoltan et al., 1999). They may undergo proton shifts (tautomerism) rapidly and easily, and the chemical reactivities of the two isomers may be quite different. Molecular assembly in a crystal is predominantly governed by intermolecular forces, conventionally described by strong and
directional $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}, \mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds (Desiraju, 2002). In molecules having an imbalance of hydrogen-bond donors and acceptors, the deficiency in either donors or acceptors is fulfilled by other types of weak and lessdirectional forces. Interactions involving the $\pi$ cloud in aromatic compounds also belong to this category. We present here the complete geometric characterization of the title compound, (I), in the solid state, together with a comparison of the molecular structure with those of related compounds and an analysis of their intermolecular interactions in the crystal network.

The asymmetric unit of (I) consists of two protonated amidinium cations, denoted $A(\mathrm{O} 1 / \mathrm{O} 2 / \mathrm{N} 1-\mathrm{N} 4 / \mathrm{C} 1-\mathrm{C} 10)$ and $B$ (O7/O8/N5-N8/C11-C20), and two dihydrogenphosphate anions, denoted $A^{\prime}$ ( $\mathrm{P} 1 / \mathrm{O} 3-\mathrm{O} 6$ ) and $B^{\prime}$ ( $\mathrm{P} 2 / \mathrm{O} 9-\mathrm{O} 12$ ). The two independent aminoguanidinium cations have very similar molecular dimensions (Fig. 1 and Table 1); this is also the case for the two dihydrogenphosphate anions, whose geometries are normal (Allen et al., 1987). In the following discussion, parameters for molecules $B$ are quoted in square brackets.

In the aminoguanidine moiety, the $\mathrm{N}-\mathrm{N}$ bond length is 1.394 (3) $\AA$ [1.395 (3) Å], approximating to a pure single bond (1.41 $\AA$; Burke-Laing \& Laing, 1976). Similarly, the corresponding $\mathrm{N}=\mathrm{C}$ bond length of 1.279 (4) $\AA[1.275$ (4) $\AA$ ] has pure double-bond character $(1.27 \AA)$. That the lone-pair electrons on atom N2 [N6] are delocalized through conjugation with the amidine group rather than the $\mathrm{N} 1=\mathrm{C} 9$

Figure 1
A view of the asymmetric unit of (I), showing the atomic numbering scheme. Displacement ellipsoids are drawn at the $30 \%$ probability level. Dashed lines indicate the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}, \mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ interactions.
[ $\mathrm{N} 5=\mathrm{C} 19$ ] double bond is also seen in the $\mathrm{N} 2-\mathrm{C} 10$ bond length of 1.335 (4) $\AA[1.329$ (4) $\AA$ ] , which is intermediate between a single and a double bond, and similar to the two $\mathrm{C}-\mathrm{N}$ bonds in the amidine moieties. Similar $\mathrm{C}-\mathrm{N}$ bond distances have been found in a number of inorganic salts containing the guanidinium cation (see, for example, Katrusiak \& Szafrański, 1994; Kettmann \& Světlík, 2002).

In the cation, the dimethoxyphenyl and aminoguanidine fragments are planar, with maximum deviations of -0.033 (3) and 0.027 (3) $\AA$ [ 0.058 (3) and 0.067 (2) $\AA$ ], respectively. The planes of these two moieties make a dihedral angle of $14.10(15)^{\circ}\left[13.46(15)^{\circ}\right]$, showing that the 2,4-dimethoxybenzylideneaminoguanidine molecules are almost flat. The 2,4-dimethoxybenzylideneaminoguanidine molecule can exist in two different configurations, as an $E$ or a $Z$ isomer, with respect to the $\mathrm{C}=\mathrm{N}$ double bond. The $\mathrm{N}-\mathrm{N}=\mathrm{C}-\mathrm{C}$ torsion angle is $-178.6(3)^{\circ}\left[176.5(3)^{\circ}\right]$, and this reveals that the molecules have the $E$-isomer structure in (I).

Within the benzene ring in the aminoguanidine $A$ molecule, there are significant differences between bond lengths: $\mathrm{C} 1-$ C6 [1.400 (4) $\AA$ ] is slightly longer than $\mathrm{C} 2-\mathrm{C} 3$ and $\mathrm{C} 4-\mathrm{C} 5$ [1.373 (4) and 1.374 (4) Å, respectively]. The remaining bond lengths in the ring are close to the $\mathrm{C} 1-\mathrm{C} 6$ bond length. In addition, the $\mathrm{C} 6-\mathrm{C} 1-\mathrm{C} 2$ bond angle is $118.4(3)^{\circ}$, while the rest of the internal angles are almost equal to the normal value of $120^{\circ}$ for the intra-ring bond angles of benzene rings. Similiar differences were also seen in the aminoguanidine $B$ molecule: C11-C16 [1.398 (4) $\AA$ ] is slightly longer than C12-C13 and C14-C15 [1.378 (4) and 1.372 (4) Å, respectively]. Moreover, the $\mathrm{C} 16-\mathrm{C} 11-\mathrm{C} 12$ bond angle is $118.0(3)^{\circ}$, while the remaining bond angles are close to $120^{\circ}$. It is interesting to note that within the dimethoxyphenyl fragment the exocyclic $\mathrm{C}-\mathrm{C}-\mathrm{O}$ angles show an unusual pattern compared with those observed for methoxyaryl compounds (Seip \& Seip, 1973; Ferguson et al., 1996; Patterson et al., 1998), in which the $\mathrm{C}-\mathrm{C}-\mathrm{O}$ angles cisoid to the substituents are much larger than $120^{\circ}$, while those transoid are very much smaller. At the same time, the $\mathrm{C}-\mathrm{O}-\mathrm{C}$ angles are well in excess of tetrahedral values, consistent with the occurrence of repulsive

Figure 2
The molecular packing of (I), showing the intermolecular interactions (dashed lines). For clarity, only H atoms involved in the hydrogen bonding have been included.
interactions between the methyl groups and the neighbouring aryl $\mathrm{C}-\mathrm{H}$ unit.

In the aminoguanidinium cation, an intramolecular N3$\mathrm{H} 3 B \cdots \mathrm{~N} 1$ [ $\mathrm{N} 7-\mathrm{H} 7 E \cdots \mathrm{~N} 5$ ] hydrogen bond leads to the formation of a five-membered ring (Fig. 1). The crystal structure of (I) is stabilized by a network of $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, in which amidine and methoxy groups, as well as $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$anions, are involved (Table 2 and Fig. 2). Additionally, there are also $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts. The $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ interactions formed between the $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$anions are quite strong. Among the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ interactions, the strongest is formed by amidine atom N2 [N6]. However, there are also one $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and one $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ interaction, in which enol O atoms are involved as acceptors. The anion O atoms are involved as acceptors in different hydrogen-bond interactions, five for $A^{\prime}$ and four for $B^{\prime}$, and hence a threecentred contact is formed. Thus, the hydrogen-bond network linking adjacent cations and anions in the crystal structure of (I) is three-dimensional. In addition to these intra- and intermolecular interactions, intermolecular $\pi-\pi$ stacking interactions between the benzene ring and its partner at $(2-x, 1-y, 1-z)$ are also observed along the $a$ axis, with a distance of 3.778 (2) A between the ring centroids. Full details of the hydrogen-bonding geometry are given in Table 2.

## Experimental

2,4-Dimethoxybenzaldehyde ( 1.66 g ) and aminoguanidinebicarbonate $(1.36 \mathrm{~g})$ were refluxed in a boiling water solution ( 20 ml ) of $1 \mathrm{NH}_{3} \mathrm{PO}_{4}$ for 1 h and, after cooling, the precipitate was collected, yielding $2.24 \mathrm{~g}(70 \%)$ of (I). The crude product was recrystallized from methanol and allowed to dry over $\mathrm{P}_{2} \mathrm{O}_{5}$ (m.p. 529 K ). Analysis calculated for $\mathrm{C}_{10} \mathrm{H}_{17} \mathrm{~N}_{4} \mathrm{O}_{6} \mathrm{P}$ : C 37.50, H 5.31, N $17.50 \%$; found: C 37.33, H 5.21, N $17.39 \%$.
