The two new title complexes, $\left[\mathrm{Cu}\left(\mathrm{N}_{3}\right)(\text { dpyam })_{2}\right] \mathrm{PF}_{6}$ (dpyam is di-2-pyridylamine, $\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{~N}_{3}$ ), (I), and $\left[\mathrm{Cu}\left(\mathrm{N}_{3}\right)(\text { dpyam })_{2}\right] \mathrm{Cl} \cdot-$ $4 \mathrm{H}_{2} \mathrm{O}$, (II), respectively, have been characterized by singlecrystal X-ray diffraction. Both complexes display a distorted square-pyramidal geometry. Each Cu atom is coordinated in the basal plane by three dpyam N atoms and one azide N atom in equatorial positions, and by another N atom from the dpyam group in the apical position. In complex (I), the onedimensional supramolecular architecture is assembled via hydrogen-bonding interactions between the amine N atom and terminal azide N atoms and the F atoms of the $\mathrm{PF}_{6}{ }^{-}$anion. For complex (II), hydrogen-bonding interactions between the amine N atom, the $\mathrm{Cl}^{-}$anion and water O atoms result in a two-dimensional lattice.

## Comment

The synthesis of pseudohalide-bridged complexes continues to be a subject of much interest, and intensive investigations have taken place as a result of their diverse structures and potential

applications in magnetic materials. Pseudohalide ligands ( $\mathrm{OCN}^{-}, \mathrm{SCN}^{-}, \mathrm{N}_{3}{ }^{-}$, etc.) can coordinate to transition metal
atoms in different ways, for example, as a terminal ligand or as a bridge (Talukder et al., 2004). One-, two- or three-dimensional supramolecular architectures assembled via intermolecular non-covalent interactions are of considerable interest for the crystal engineering of new functional solidstate materials, as well as for their fascinating structures (Gao et al., 2001). Hydrogen bonding, which combines directionality, selectivity and strength, has been noted as the most versatile organizing force for supramolecular assembly (Chen et al., 2001). We report here the two new title complexes, $\left[\mathrm{Cu}\left(\mathrm{N}_{3}\right)(\text { dpyam })_{2}\right] \mathrm{PF}_{6}$, (I), and $\left[\mathrm{Cu}\left(\mathrm{N}_{3}\right)(\text { dpyam })_{2}\right] \mathrm{Cl} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, (II). The dpyam ligand has been selected primarily because it also has an $\mathrm{N}-\mathrm{H}$ hydrogen-bond donor function that might produce one-, two- or three-dimensional supramolecular architectures.

The crystal structures of (I) and (II) (Figs. 1 and 2) consist of a $\left[\mathrm{Cu}\left(\mathrm{N}_{3}\right)(\text { dpyam })_{2}\right]^{+}$cation and $\mathrm{PF}_{6}^{-}$and $\mathrm{Cl}^{-}$anions,

Figure 1
The molecular structure of (I), showing $30 \%$ probability displacement ellipsoids and the atom-numbering scheme. H atoms are shown as small spheres of arbitrary radii. Only one of the disordered components of the $\mathrm{PF}_{6}{ }^{-}$anion is shown.

Figure 2
The molecular structure of (II), showing $30 \%$ probability displacement ellipsoids and the atom-numbering scheme. H atoms are shown as small spheres of arbitrary radii.
respectively. The Cu atoms of both molecules exhibit fivecoordination of the $\mathrm{CuN}_{4} \mathrm{~N}^{\prime}$ chromophore (see scheme). The coordination around each Cu atom consists of three dpyam N atoms and one azide N atom in equatorial positions, and another N atom from dpyam in the apical position. Both complexes exhibit a slightly distorted square-pyramidal environment, the geometric $\tau$ values (Addison et al., 1984) being 0.061 for (I) and 0.148 for (II). The average $\mathrm{Cu}-\mathrm{N}$ distances (Tables 1 and 3) in the equatorial positions are 2.017 (1) $\AA$ for (I) and 2.009 (1) $\AA$ for (II). The axial $\mathrm{Cu}-\mathrm{N}$ distances are longer, at 2.153 (2) $\AA$ for (I) and 2.169 (2) $\AA$ for (II). The Cu atoms are displaced by 0.264 (1) $\AA$ for (I) and 0.255 (1) $\AA$ for (II) from the mean basal plane towards the apical position. The dpyam ligands are not planar, with dihedral angles between the two pyridine rings of 34.4 (1) and 16.1 (1) ${ }^{\circ}$ for (I), and 35.3 (1) and 14.6 (1) ${ }^{\circ}$ for (II).

There are extensive hydrogen-bonding interactions in both structures. In complex (I), intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{F}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ (azide) hydrogen-bonding interactions (Table 2) produce a one-dimensional chain (Fig. 3). The crystal packing of complex (II) is stabilized by intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$, $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ (azide), $\mathrm{O}-\mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen

A packing diagram for (I), with hydrogen bonds (dashed lines), showing the one-dimensional structure.

Figure 4
A packing diagram for (II), with hydrogen bonds (dashed lines), showing the two-dimensional structure.
bonds (Table 4), leading to a two-dimensional supramolecular structure (Fig. 4).

The chromophores of (I) and (II) are very similar except for the four additional water molecules in the structure of complex (II), which create a two-dimensional hydrogenbonded network in (II).

## Experimental

Complex (I) was prepared by adding a warm solution of di-2pyridylamine ( $0.17 \mathrm{~g}, 1.00 \mathrm{mmol}$ ) in methanol ( 15 ml ) to a hot aqueous solution ( 10 ml ) containing $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}(0.091 \mathrm{~g}$, $0.5 \mathrm{mmol})$ and $\mathrm{NaN}_{3}(0.065 \mathrm{~g}, 1.0 \mathrm{mmol})$. An aqueous solution $(15 \mathrm{ml})$ of $\mathrm{KPF}_{6}(0.184 \mathrm{~g}, 1.0 \mathrm{mmol})$ was then added, giving a clear green solution. The resulting solution was evaporated slowly at room temperature. After several days, green needle-shaped crystals of (I) which had formed were filtered off, washed with mother liquor and air-dried (yield ca $90 \%$ ). Green needle-shaped crystals of (II) were obtained by adding a warm solution of di-2-pyridylamine ( 0.171 g , 1.0 mmol ) in methanol ( 15 ml ) to a boiling aqueous solution ( 15 ml ) of $\mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(0.085 \mathrm{~g}, 0.5 \mathrm{mmol}) . \mathrm{NaN}_{3}(0.130 \mathrm{~g}, 2.0 \mathrm{mmol})$ was then added to the reaction mixture. After several days, crystals of (II) which had formed were filtered off, washed with mother liquor and air-dried (yield ca $85 \%$ ). The electronic reflectance spectra of both complexes involve main peaks at 14050 and $14000 \mathrm{~cm}^{-1}$, and lower energy shoulders at 11010 and $11110 \mathrm{~cm}^{-1}$ for (I) and (II), respectively. These spectroscopic characteristics of the compounds are consistent with a distorted square-pyramidal geometry with a small $\tau$ value. The transitions may be assigned as the $d_{z^{2}} \rightarrow d_{x^{2}-y^{2}}$ transition for the low-energy shoulder and the $d_{x z} \sim d_{y z} \rightarrow d_{x^{2}-y^{2}}$ transition for the high-energy peak. The strongest intensity features in the spectra of (I) and (II) appear at 2042 and $2040 \mathrm{~cm}^{-1}$, respectively, together with sharp and medium intensity peaks at 2035 and $2034 \mathrm{~cm}^{-1}$, respectively, attributed to $v_{\text {as }}\left(N_{3}\right)$. For the IR spectrum of sodium azide, a single strong peak at $2033 \mathrm{~cm}^{-1}$ is observed. Hence, in the present compounds, the shift towards higher wavenumbers of the $v_{\text {as }}$ stretching of the azide indicates that it must be coordinated.

In (I), H atoms attached to N3 and N6 were located in a difference Fourier map and refined with a DFIX (SHELXTL; Sheldrick, 2000b) restraint of $\mathrm{N}-\mathrm{H}=0.86$ (1) $\AA$. The remaining H atoms were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}=0.93 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$. The F atoms of the hexafluorophosphate group showed disorder; the occupancies of the disordered positions were initially refined and later fixed at 0.5 . In (II), H atoms attached to water O atoms were located in difference Fourier maps and refined with a DFIX restraint of $\mathrm{O}-\mathrm{H}=$ 0.90 (1) $\AA$. The remaining H atoms were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}=0.93 \AA$ and $\mathrm{N}-\mathrm{H}=0.86 \AA$, and with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C}, \mathrm{N})$.
