The structure of *trans*-3-(3-pyridyl)acrylic acid,  $C_8H_7NO_2$ , (I), possesses a two-dimensional hydrogen-bonded array of supramolecular ribbons assembled *via* heterodimeric synthons between the pyridine and carboxyl groups. This compound is photoreactive in the solid state as a result of close contacts between the double bonds of neighbouring molecules [ $3.821(1) \text{ \AA}$ ] along the *a* axis. The crystal structure of the photoproduct, *rac*-3,3'-(3,4-dicarboxycyclobutane-1,2-diyl)-dipyridinium dichloride,  $C_{16}H_{16}N_2O_4^{2+} \cdot 2Cl^-$ , (II), consists of a three-dimensional hydrogen-bonded network built from crosslinking of helical chains integrated by self-assembly of dipyridinium cations and  $Cl^-$  anions *via* different  $O-H \cdots Cl$ ,  $C-H \cdots Cl$  and  $N^+ - H \cdots Cl$  hydrogen-bond interactions.

### Comment

Organic reactions performed in the solid state are considered an important green alternative for the preparation of new and conventional compounds (Toda, 2005; MacGillivray *et al.*, 2004; Gao *et al.*, 2004; Tanaka & Toda, 2000; Xiao *et al.*, 2000; Garcia-Garibay, 2003; Ramamurthy & Venkatesan, 1987; Díaz de Delgado *et al.*, 1991). A particular case of solid-state reactions is [2+2]-photocycloaddition, in which the nature and features of the products can be controlled by topochemical parameters (Schmidt, 1971). This alternative offers regio- and stereoselective control combined with quantitative yields. These advantages make the assembly of olefins in the solid state an efficient route for regiocontrolled access to versatile multitopic organic molecules. Such compounds turn out to be very interesting as building blocks for designing novel supramolecular metal assemblies with unusual topologies (Papaefstathiou & MacGillivray, 2002; Papaefstathiou, Milios & MacGillivray, 2004; Papaefstathiou, Hamilton *et al.*, 2004; Papaefstathiou *et al.*, 2005; Lee *et al.*, 2005; Kim & Jung, 2002). As part of our interest in the study of potentially thermally

and photoreactive solids (Briceño *et al.*, 2006, 2002, 1999), we have re-investigated the photoreactivity of *trans*-3-(3-pyridyl)acrylic acid, (I), to prepare a tetratopic ligand containing either pyridyl or carboxyl groups. The solid-state reactivity of (I) was previously studied by Lahav & Schmidt (1967). However, neither the crystal structure of the starting material nor that of the dimer have yet been reported in the literature. Here, the crystal structures of (I) and a hydrogen-bonded supramolecular array based on the photoproduct, (II), are reported.

The molecule of (I) (Fig. 1) adopts a nearly planar conformation, with a maximum deviation from the mean molecular plane of  $0.007(2) \text{ \AA}$ . The molecule displays an intramolecular  $C-H \cdots O$  hydrogen bond [ $C \cdots O = 2.765(2) \text{ \AA}$  and  $C3-H3 \cdots O1 = 102^\circ$ ], which leads to the formation of a five-membered ring described by the  $S(5)$  graph-set symbol (Bernstein *et al.*, 1995).

The crystal structure of (I) consists of the self-assembly of molecules *via* a heterodimeric hydrogen-bonded synthon based on the interaction between the pyridyl and carboxyl

**Figure 1**  
The molecular structure of (I), showing the atom-labelling scheme and the intramolecular hydrogen bond (dashed line). Displacement ellipsoids are drawn at the 30% probability level and H atoms are shown as small spheres of arbitrary radii.

**Figure 2**  
(a) A view of the hydrogen-bonded network observed in the crystal structure of (I). (b) Close contacts between adjacent molecules along the *a* axis. [Symmetry codes: (i)  $1 - x, -\frac{1}{2} + y, \frac{3}{2} - z$ ; (ii)  $-x, 1 - y, 1 - z$ .]

groups. This supramolecular motif, described as  $R_2^2(7)$ , is repeated along the  $b$  direction to generate zigzag supramolecular ribbons with distances  $O1 \cdots N1^i = 2.660(2) \text{ \AA}$  and  $C5 \cdots O2^i = 3.263(2) \text{ \AA}$  [symmetry code: (i)  $1 - x, -\frac{1}{2} + y, \frac{3}{2} - z$ ]. Adjacent ribbons are linked by two complementary  $C-H \cdots O$  hydrogen bonds [ $C8 \cdots O2^{ii} = 3.299(3) \text{ \AA}$ ; symmetry code: (ii)  $-x, 1 - y, 1 - z$ ]. These interactions induce self-assembly of parallel ribbons in an alternating head-to-tail fashion, resulting in a two-dimensional hydrogen-bonded array in the  $bc$  plane (Fig. 2a). The three-dimensional network is achieved by stacking of the sheets through  $\pi$ - $\pi$  interactions along the  $a$  axis (interlayer distance  $ca$  3.8  $\text{ \AA}$ ).

A remarkable feature of the structure of (I) is the presence of close contacts between the double bonds of neighbouring molecules related by translation along the  $a$  axis [centroid-to-centroid distance = 3.812(1)  $\text{ \AA}$ ]. This structural feature is responsible for the photoreactivity that is displayed by (I) in the solid state (Fig. 2b).

As expected, UV irradiation of (I) produces the dimer. The  $^1\text{H}$  NMR spectrum confirms the photocycloaddition (see *Experimental*). The stereochemistry of the product was

**Figure 3**  
The molecular structure of the dication of (II), showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 30% probability level and H atoms are shown as small spheres of arbitrary radii.

**Figure 4**  
A view along the  $a$  axis of the one-dimensional helical chains generated by  $O-H \cdots Cl$  interactions (dashed lines). Most H atoms have been omitted for clarity. [Symmetry codes: (i)  $x + \frac{1}{2}, -y + \frac{1}{2}, -z + 2$ ; (viii)  $-x - \frac{1}{2}, -y + \frac{1}{2}, -z + 2$ ].

confirmed by single-crystal structure analysis, which revealed the formation of a typical truxinic acid analogue (head-to-head dimer). This result is in agreement with the expected topochemical control by the crystalline starting material, and with the results previously reported by Lahav & Schmidt (1967) based on the characterization of the compound by  $^1\text{H}$  NMR spectroscopy and other chemophysical observations.

The asymmetric unit of (II) consists of the diprotonated  $\beta$ -dimer (Fig. 3) and two  $Cl^-$  anions. The cyclobutane ring is slightly puckered; the C4 flap atom deviates by 0.354(5)  $\text{ \AA}$  from the plane of the other three atoms of the four-membered ring. This value is similar to those observed for other substituted cyclobutanes that do not crystallize on a centre of symmetry (Abdelmoty *et al.*, 2005; Kanao *et al.*, 1990; Pani *et al.*, 1995). Both pyridinium rings, as well as the carboxyl groups, are twisted out of the mean plane of the cyclobutane ring: the mean planes of the pyridinium rings based on N1 (C7–C11) and N2 (C12–C16), and carboxyl groups O1/C5/O2 and O4/C6/O3, are rotated by 69.0(1), 79.1(1), 35.9(3) and 86.2(3) $^\circ$ , respectively (Fig. 3).

An analysis of the bond distances and angles of the pyridyl rings in (I) and (II) only reveals significant differences in the internal  $C-N-C$  angle of both protonated N atoms. These values are greater in (II) than in (I) (Tables 1 and 2).

The structure of (II) consists of a three-dimensional hydrogen-bonded network built up by self-assembly of the cations and  $Cl^-$  anions *via* different  $C-H \cdots Cl$ ,  $O-H \cdots Cl$  and  $N-H \cdots Cl$  hydrogen-bond interactions. In this structure, the  $Cl^-$  anions act as structure-directing agents of this assembly, and each  $Cl^-$  anion is an acceptor of multiple hydrogen-bond interactions. Atom Cl1 is an acceptor of four hydrogen bonds from different adjacent dications, whereas atom Cl2 accepts only three hydrogen bonds. Details of the hydrogen-bonding geometry in (II) are given in Table 2. The cations are self-assembled through  $O-H \cdots Cl$  interactions

**Figure 5**  
A view of the crystal structure of (II) in the  $bc$  plane, showing  $C-H \cdots Cl$ ,  $O-H \cdots Cl$  and  $N-H \cdots Cl$  interactions (dashed lines). Most H atoms have been omitted for clarity. The darker molecules indicate one of the neighbouring helical arrangements (see *Comment*).

between carboxyl groups and Cl1 atoms, generating one-dimensional helical chains running along the *a* axis (Fig. 4). The central axis about each chain is a twofold screw axis. Neighbouring helical arrangements (shown dark in Fig. 5) are crosslinked by additional N<sup>+</sup>—H···Cl hydrogen bonds, involving pyridinium units through the H atom of the protonated ring, and C—H···Cl interactions, to afford a three-dimensional hydrogen-bonded assembly (Fig. 5).

## Experimental

*trans*-3-(3-Pyridyl)acrylic acid, (I), was obtained commercially (Aldrich). Crystals were obtained by slow evaporation of a methanol solution. IR (KBr disc,  $\nu$ , cm<sup>-1</sup>): 3500–2300 (O—H), 3052 (=C—H), 1702 (C=O), 1635 (C=C), 1580 and 1418 (C=C and C=N), 1284 (C—O). The photodimer was prepared by topochemical reaction of (I). Crystals and a powdered crystalline material of (I) were irradiated with a 100 W Hg lamp above 302 nm for 3 d. The product was purified as described in the literature (Lahav & Schmidt, 1967) (yield 55–60%). IR (KBr,  $\nu$ , cm<sup>-1</sup>): 3500–2300 (O—H), 3057 (=C—H), 2955–2857 (C—H), 1717 (C=O), 1583 and 1422 (C=C and C=N), 1277 (C—O); <sup>1</sup>H NMR (*d*<sub>6</sub>-DMSO):  $\delta$  8.25 (2H, *s*, *J* = 1.86 Hz), 8.17 (2H, *d*, *J* = 3.84 Hz), 7.45 (2H, *d*, *J* = 6.24 Hz), 7.08 (2H, *dd*, *J* = 7.83 Hz), 4.25 (2H, *d*), 3.89 (2H, *d*, *J* = 6.24 Hz). Crystals of (II) were obtained by dissolving the dimer (200 mg) in distilled water (50 ml) and adjusting the pH to 1 with HCl. The resultant solution was allowed to evaporate slowly at room temperature. After 2–3 weeks, pale-yellow crystals suitable for X-ray analysis had formed. Attempts were made to optimize the exposure time, and thus ensure the maximum yield, by monitoring the degree of conversion of the photoreaction by FT-IR spectroscopy. It was found that compound (I) in the presence of KBr is photodegraded by decarboxylation. Interestingly, the CO<sub>2</sub> released is partially trapped in the KBr disc. The CO<sub>2</sub> band is enhanced as a function of the exposure time, and simultaneously a decrease in the relative intensity of the absorption band corresponding to the C=O stretch at 1702 cm<sup>-1</sup> was observed. After 4 h of irradiation, a loss of resolution in the FT-IR spectrum was observed. This behaviour was not observed during direct UV irradiation of (I); apparently, the KBr matrix induced this process.
