For charge balance in the title compound, $(\text{H}_5\text{O}_2^+)(\text{C}_3\text{H}_7\text{N}_6)_3\text{-}[\text{Mn}(\text{C}_7\text{H}_3\text{NO}_4)_2(\text{OH})\cdot\text{C}_7\text{H}_5\text{NO}_4\cdot 5\text{H}_2\text{O}]$, it is assumed that the metal atom site is disordered $\text{Mn}^{\text{II}}/\text{Mn}^{\text{III}}$, probably due to partial air oxidation of the starting Mn^{II} species. The formula unit of the complex contains a hydroxonium hydrate cation, H_5O_2^+ , also known as the Zundel cation, with twofold symmetry. The $\text{O}\cdots\text{O}$ [2.445 (10) Å] and $\text{O}\cdots\text{H}$ distances [1.24 (2) Å] in the H_5O_2^+ cation indicate a strong hydrogen bond. In addition, there is a hydroxide ion that is disordered with respect to a twofold rotation axis. One of the melaminium groups and the pyridine-2,6-dicarboxylate (pydc) ligand also reside on crystallographic twofold axes. The coordination environment of the Mn ion is distorted octahedral. Three intermolecular $\text{C}=\text{O}\cdots\pi$ interactions are observed, with distances of 3.536 (4), 3.262 (4) and 3.750 (4) Å between carboxylate $\text{C}=\text{O}$ groups and the centroids of the aromatic rings of pydc and melaminium. There are numerous $\text{O}-\text{H}\cdots\text{O}$, $\text{O}-\text{H}\cdots\text{N}$, $\text{N}-\text{H}\cdots\text{O}$, $\text{N}-\text{H}\cdots\text{N}$ and $\text{C}-\text{H}\cdots\text{O}$ hydrogen bonds. Most of the components of the structure are organized into one plane.

Comment

Melamine, used in the synthesis of plastics, has recently been implicated in the food industry as an impurity in powdered milk and pet food products and as a causative agent in the production of kidney stones in infants and in pets. With oxalic acid, one of the main constituents of kidney fluids, a proton-transfer salt of [melaminium H_2][$\text{C}_2\text{O}_2\text{H}$]₂ is formed (Zhang *et al.*, 2005). Melamine is also known to form melaminium H_2^{2+} salts with trifluoroacetic acid (Perpétuo & Janczak, 2006) and other strong acids. With somewhat weaker acids, such as pyridine-2,6-dicarboxylic acid (pydc H_2), both the mono- and

diprotonated species have been described (Sharif *et al.*, 2006). It is pertinent to study these proton-transfer salts in combination with metal ions in order to model the biological species that may exist in kidney disease. The crystal structures of metal complexes involving Cd^{II} (Aghabozorg, Aghajani & Sharif, 2006), Zn^{II} (Aghajani *et al.*, 2006), Bi^{III} (Sharif, Aghabozorg & Moghimi, 2007), Pb^{II} (Sharif *et al.*, 2006), Co^{II} (Aghabozorg *et al.*, 2008) and Ni^{II} (Sharif, Aghajani & Aghabozorg, 2007) are known. In the asymmetric unit of the title compound, (I), one-and-a-half molecules of melamine are each monoprotonated and crystallize with bis(pyridine-2,6-dicarboxylato)manganate(II/III), a neutral molecule of pydc H_2 , one-half of a H_5O_2^+ cation, one-half of a hydroxide anion and two-and-a-half molecules of water. Although it is beyond the scope of this report to compare all the metal complexes, it is significant that the synthesis of these complexes can be accomplished by a one-pot method, mixing acid, base and simple metal salt to form crystalline products. We were surprised to find that the product material in this case contains the Zundel cation, H_5O_2^+ , and that the Mn atom is apparently in a disordered mixed-valent $\text{Mn}^{\text{II}}/\text{Mn}^{\text{III}}$ state. Both Mn^{II} and Mn^{III} complexes of salts of the bis complex, $\text{Mn}(\text{pydc})_2$, have been described previously, for example, with Mn^{II} (MacDonald *et al.*, 2004; Aghabozorg, Ghasemikhah *et al.*, 2006) and with Mn^{III} (Limburg *et al.*, 1997).

Compound (I) is depicted in Fig. 1. The Mn atom is hexacoordinated by two N atoms (N1 and N2) and four O atoms (O1, O3, O5 and O7) from carboxylate groups of two pydc groups in a distorted octahedral arrangement. The dihedral angle between these two coordinated pydc groups is 88.63 (5)°, which shows that the ligands are almost perpendicular to each other. For charge balance, it was assumed that the metal atom site is disordered $\text{Mn}^{\text{II}}/\text{Mn}^{\text{III}}$, probably due to partial air oxidation of Mn^{II} . However, this assumption has not been confirmed by any noncrystallographic methods. No difference-map peaks satisfied the alternative models, *i.e.* that the melaminium H^+ was melaminium H_2^{2+} or that one of the coordinated carboxylate groups or water molecules was protonated.

The Mn—N and Mn—O distances (Table 1) are longer than those seen in related Mn^{III} complexes, which average 2.020 (8) and 2.01 (13) Å, respectively (Limburg *et al.*, 1997; Huang *et al.*, 2004). However, they are also shorter than the average of 34 observations [Cambridge Structural Database (CSD), *ConQuest* Version 1.10; Allen, 2002) for Mn^{II} in pydc coor-

Figure 1

A view of the various constituents of (I), showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 30% probability level and H atoms are shown as small spheres of arbitrary radii. [Symmetry codes: (i) $-x, y, -\frac{1}{2} - z$, (ii) $-x, y, \frac{1}{2} - z$.]

dination compounds, namely 2.22 (6) and 2.30 (7) Å for Mn–N and Mn–O, respectively (CSD refcodes BIPJER, EJAMEH, IHELAI, LOYYON, LOYYUT, MABNIN, MABNOT, NEQPEF, QARZEP, SAQQUX, XEGDIW, XENJEG, MIGZEI and XIMHAD).

The formula unit of the complex contains one H_5O_2^+ cation that resides on a twofold rotation axis. One of the melaminium H^+ groups and the pydc also reside on crystallographic twofold axes. In addition, there is an OH^- (O15–H15) ion that is disordered with respect to a twofold rotation axis.

There are three notable $\text{C}=\text{O} \cdots \pi$ intermolecular interactions between C=O groups and the centroids of the aromatic rings of pydc and melaminium H^+ (Table 3). As shown in Fig. 2, the packing of the structure can be described by layers that contain almost all the constituent species. The main parts that are not in these layers are the perpendicular pydc ligands. By reference to Fig. 1, the hydrogen bonding that

leads to these layers can be envisioned. A notable grouping of two melaminium H^+ cations, water and pydc yields seven strong hydrogen bonds.

In pet food contamination studies involving dogs and cats (Filigenzi *et al.*, 2008), melamine and its metabolites are present in kidney tissue. In consideration of the number of intermolecular interactions present in this and similar structures and the rich carboxylic acid environment in the kidneys, the pathology of melamine is not at all surprising.

Experimental

The reaction between solutions of pyridine-2,6-dicarboxylic acid (pydc H_2 ; 100 mg, 1 mmol) in water (10 ml), 2,4,6-triamino-1,3,5-triazine (melamine) (110 mg, 1 mmol) in water (10 ml) and $\text{Mn}(\text{CH}_3\text{COO})_2$ (72 mg, 0.5 mmol) in water (5 ml) in a 2:2:1 molar ratio gave pale-yellow needles after slow evaporation of the solvent at room temperature.

Symmetry codes: (i) $x + \frac{1}{2}, -y + \frac{3}{2}, z + \frac{1}{2}$; (ii) $x + \frac{1}{2}, y + \frac{1}{2}, z$; (iii) $-x, y, -z - \frac{1}{2}$; (iv) $-x, y, -z + \frac{1}{2}$; (v) $-x, -y + 1, -z$; (vi) $x, y, z - 1$; (vii) $x + \frac{1}{2}, -y + \frac{3}{2}, z - \frac{1}{2}$; (viii) $-x, y, -z + \frac{3}{2}$; (ix) $-x, -y + 2, -z + 1$.

C- and N-bound H atoms were positioned geometrically, with C—H = 0.95 Å and N—H = 0.88 Å, and allowed to ride on their parent atoms, with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. O-bound H atoms were located in a difference Fourier map and allowed to refine with distance restraints of O—H = 0.84 (1) Å and H...H (in water) = 1.30 (2) Å, except for atom H12E, part of the H_5O_2^+ cation, which resides on a twofold axis and was not restrained. This atom was freely refined but displays a large isotropic displacement parameter of 0.11 Å² that causes an Alert A in *checkCIF* and we suggest that it is slightly disordered with respect to its position on the twofold axis. The H atom bonded to O15, part of the OH[−] ion that is disordered with respect to the
