In the title compound, $C_9H_4F_9O_2P$, molecules are linked by a single $O-H\cdots O$ hydrogen bond into chains related to those in phenylphosphinic acid. There are short intramolecular $F\cdots P$ contacts.

Comment

Several group 15 halides containing the 2,4,6-tris(trifluoromethyl)phenyl (*Ar*) ligand have been described, some of which have been characterized crystallographically, including phosphorus, arsenic, antimony and bismuth compounds (Batsanov *et al.*, 2002; Burford *et al.*, 2000; Whitmire *et al.*, 1991). Although the compound $ArPCl_2$ has been synthesized and characterized by ^{31}P and ^{19}F NMR spectroscopy (Dillon *et al.*, 1988; Scholz *et al.*, 1989), single crystals have not been isolated so far; however, the hydrolysis product [2,4,6-tris(trifluoromethyl)phenyl]phosphinic acid, $ArP(O)H(OH)$, (I), has now been crystallized. This compound is believed to be formed by rearrangement of the initial phosphorus(III) hydrolysis product $ArP(OH)_2$ to the more stable phosphorus(V) form, with a $P=O$ double bond and a $P-H$ bond as, for example, in phosphorous acid, H_3PO_3 , which has the structure $P(O)H(OH)_2$ in solution and which behaves as a dibasic rather than as a tribasic acid.

Compound (I) (Fig. 1) crystallizes in the noncentrosymmetric space group $P2_1$ and shows signs of inversion twinning: the Flack x parameter (Flack, 1983) refined to 0.24 (16), although analysis of the Bijvoet differences using PLATON

(Spek, 2009) gave the Hooft y parameter as 0.16 (8), indicating that the probability that the configuration is correct is greater than 0.999 and the probability of an inversion twin is 8×10^{-4} (Hooft *et al.*, 2008). Each $P-OH$ group is hydrogen bonded to the $O=P$ group of an adjacent molecule (Table 1), forming a chain along $[010]$ (Fig. 2). This hydrogen-bonding motif is similar to that seen in phenylphosphinic acid (Burrow *et al.*, 2000), although the chains in (I) propagate along a 2_1 screw axis, whereas in phenylphosphinic acid the chains are propagated along the a axis by glide planes. The chains in (I) pack together to form a herring-bone-type motif around the 2_1 axes, which leads to short intermolecular $F\cdots F$ contacts [2.870 (4)–2.926 (4) Å] and may perhaps explain why the $p-CF_3$ group, although displaying slightly elevated anisotropic displacement parameters, appears to be less mobile than observed in many related materials (Batsanov *et al.*, 2002, 2003; Cornet *et al.*, 2003).

The hydrogen-bonded $O\cdots O$ distance in (I) is comparable with those in phenylphosphinic acid, ethylenebis(phosphinic acid) and methylenebis(phosphinic acid), and also in the 1:1 mixture of [2-(diphenylphosphino)phenyl]phosphinic acid and its dimethylammonium salt (Table 2; Burrow *et al.*, 2000; Bruckmann *et al.*, 1999; King *et al.*, 1986; Kottsieper *et al.*, 2001), and corresponds to a strong hydrogen bond. Slightly

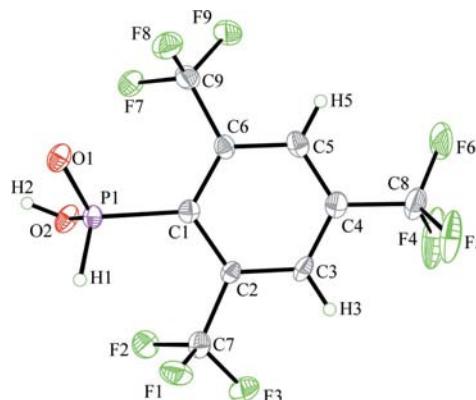

Figure 1

The molecular structure of (I), showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 50% probability level.

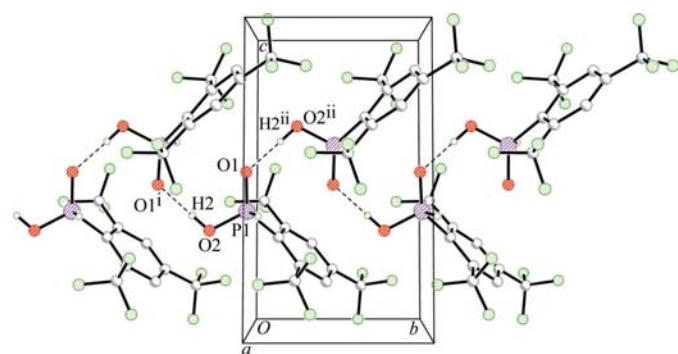

Figure 2

A hydrogen-bonded chain in (I). For the sake of clarity, H atoms bonded to C atoms have been omitted, but the H atom bonded to P is included. [Symmetry codes: (i) $1-x, -\frac{1}{2}+y, 1-z$; (ii) $1-x, \frac{1}{2}+y, 1-z$.]

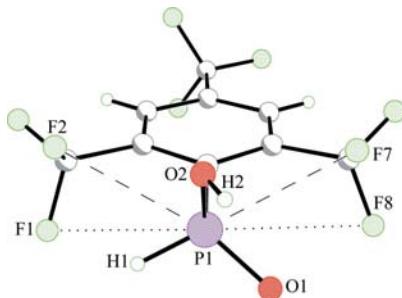

Figure 3

The intramolecular $F \cdots P$ interactions in (I). The stronger interactions are shown with broken lines and the longer distances are shown with dotted lines.

longer $O \cdots O$ contacts, between 2.62 and 2.69 Å, were found in $\{[C_5H_5NH]^+[PhP(O)(H)O]^-_2\} \cdot 3F_3CC(OH)_2CF_3$ (Goerlich *et al.*, 1995); the $P=O$ and $P-O$ bond lengths are also comparable with those in these phosphinic acids (Table 2).

Another interesting feature of the structure is the existence of short intramolecular contacts between two F atoms, in particular (F2 and F7) of the *o*- CF_3 groups, and the P atom, at distances of 2.922 (2) and 2.915 (2) Å, respectively (Fig. 3). This is appreciably shorter than the sum of the empirical van der Waals radii of P (1.91 Å) and F (1.40 Å) (Zefirov & Zorkii, 1989), as well as of the theoretical radii, estimated as 2.05 and 1.42 Å, respectively (Franck *et al.*, 1984). The next nearest F atoms, F1 and F8, are at 3.356 (2) and 3.5341 (2) Å, respectively, from the P atom and would thus not appear to have significant interactions. Short $P \cdots F$ contacts, between 2.843 and 3.250 Å, have been found previously in other aryl-phosphorus compounds with one or two *o*- CF_3 groups on the aromatic ring (see Table 3).

Similar short $E-F$ distances have been reported in the 2,4,6-(CF_3)₃C₆H₂ (*Ar*), 2,6-(CF_3)₂C₆H₃ (*Ar'*) and 2,4-(CF_3)₂C₆H₃ [*Ar''*; *o*-(CF_3) group only] derivatives of elements in group 14 (Si, Ge, Sn and Pb; Grützmacher *et al.*, 1991, 1992, 1994; Brooker *et al.*, 1991; Lay *et al.*, 1992; Buijink *et al.*, 1993; Grützmacher & Pritzkow, 1993; Vij *et al.*, 1994; Van der Maelen Uría *et al.*, 1994; Braddock-Wilking *et al.*, 1995; Freitag *et al.*, 1995; Bender *et al.*, 1997, 1998, 1999; Klinkhammer *et al.*, 1998), group 15 (As and Sb, as well as P; Burford *et al.*, 2000; Batsanov *et al.*, 2002; Cornet *et al.*, 2004), group 16 [Se and Te (Voelker *et al.*, 1999); Zn, Cd and Hg (Brooker *et al.*, 1992); Li (Stalke & Whitmire, 1990); B (Toyota *et al.*, 2000; Cornet *et al.*, 2003)].

They have also been reports of similar derivatives of V (Gibson *et al.*, 1996), Cr (Batsanov, Dillon *et al.*, 2001), Mo (Dillon *et al.*, 1997; Batsanov, Dillon *et al.*, 2001) and Ni (Benedikt *et al.*, 2001), although the $M-F$ distances in Pd^{II} derivatives (Bartolomé *et al.*, 1996), and in Au^I and Au^{III} compounds (Espinet *et al.*, 2000) were considered to be essentially nonbonding. In systems where such short contacts have been found, they have generally been regarded as contributing to the overall stabilities of the species concerned, and that is expected to be true for the title compound. There are also the following short contacts in the title

compound: $F1 \cdots H1$ [2.46 (4) Å], $F2 \cdots H1$ [2.44 (3) Å], $F2 \cdots O2$ [2.944 (3) Å], $F7 \cdots O1$ [2.766 (3) Å] and $F7 \cdots O2$ [2.978 (4) Å].

Experimental

Crystals of the title compound were obtained by slow hydrolysis of a solution of $ArPCl_2$ (Dillon *et al.*, 1988; Scholz *et al.*, 1989) in a $CH_2Cl_2/CDCl_3$ mixture in an NMR tube. NMR: $\delta(H)$ 8.21 (s, aromatic C—H), 8.06 (d, $^1J_{PH} = 618$ Hz, H—P), 5.90 (s, br, HO—P); $\delta(F)$ —55.9 (d, $^4J_{PF} = 6.4$ Hz, *o*- CF_3), —64.1 (s, *p*- CF_3); $\delta(P)$ 14.0 (d, $^1J_{PH} = 625$ Hz). The ^{31}P NMR data are very similar to those recorded for 2,6-(CF_3)₂C₆H₃PH(O)OH [$\delta(P)$ 9.50 (d, $^1J_{PH} = 600$ Hz); Karlstedt *et al.*, 1992]; comparable values have also been reported for MePH(O)OH [$\delta(P)$ 35.0 (d, $^1J_{PH} = 557$ Hz); Gallagher, 1991], PhPH(O)OH [$\delta(P)$ 20 (d, $^1J_{PH} = 560$ Hz); Gallagher, 1991] and 2,4,6-*t*Bu₃C₆H₂PH(O)OH [$\delta(P)$ 25.7 (d, $^1J_{PH} = 576$ Hz); Yoshifuji *et al.*, 1983].
