The title compound, poly[[ $\mu$-cyanoureato-tri- $\mu$-hydroxidodicopper(II)] dihydrate], $\left\{\left[\mathrm{Cu}_{2}\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{~N}_{3} \mathrm{O}\right)(\mathrm{OH})_{3}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$, is a new layered copper(II) hydroxide salt (LHS) with cyanoureate ions and water molecules in the interlayer space. The three distinct copper(II) ions have distorted octahedral geometry: one Cu (symmetry $\overline{1}$ ) is coordinated to six hydroxide groups $(4 \mathrm{OH}+2 \mathrm{OH})$, whilst the other two Cu atoms (symmetries $\overline{1}$ and 1) are coordinated to four hydroxides and two N atoms from nitrile groups of the cyanoureate ions $(4 \mathrm{OH}+2 \mathrm{~N})$. The structure is held together by hydrogen-bonding interactions between the terminal - $\mathrm{NH}_{2}$ groups and the central cyanamide N atoms of organic anions associated with neighbouring layers.

## Comment

In addition to the much studied layered double hydroxides (LDH), such as hydrotalcite, $\mathrm{Mg}_{6} \mathrm{Al}_{2}(\mathrm{OH})_{16}\left(\mathrm{CO}_{3}\right) \cdot 4 \mathrm{H}_{2} \mathrm{O}$, and related transition-metal substituted phases (Rives, 2001; Evans \& Slade, 2006), a second class of materials with structures derived from brucite, $\operatorname{Mg}(\mathrm{OH})_{2}$, namely the layered metal hydroxide salts (LHS), are gaining in scientific and technological importance (Arizaga et al., 2007). This results from their potential uses as anion exchangers, catalysts and two-dimensional magnetic materials (Laget et al., 1998, 1999; Yamanaka et al., 1992). The LHS have the general formula $M^{2+}(\mathrm{OH})_{2-x}\left(A^{m-}\right)_{x / m} \cdot n \mathrm{H}_{2} \mathrm{O}$, where $M$ is a divalent metal and $A$ is a counter-anion; examples include $M_{2}(\mathrm{OH})_{3}(A)(M=\mathrm{Co}$, $\left.\mathrm{Ni}, \mathrm{Cu} ; A=\mathrm{Cl}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{CH}_{3} \mathrm{COO}^{-}\right), \mathrm{Cd}(\mathrm{OH}) \mathrm{NO}_{3} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Zn}_{5}(\mathrm{OH})_{8}\left(\mathrm{NO}_{3}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Arizaga et al., 2007). Most pertinent to this work are the copper hydroxide salts, $\mathrm{Cu}_{2}(\mathrm{OH})_{3}(A)$, where $A$ can be a simple anion, as above, or a long-chain organic anion, such as an alkylsulfonate $\left(n-\mathrm{C}_{m} \mathrm{H}_{2 m+1} \mathrm{OSO}_{2}{ }^{-}\right.$; Park \& Lee, 2005) or alkylcarboxylate ( $n-\mathrm{C}_{m} \mathrm{H}_{2 m+1} \mathrm{COO}^{-}$; Fujita \& Awaga, 1996, 1997). Adjusting the alkyl chain length in the organic anions enables the magnetic behaviour of the layered materials to be tuned by changing the relative importance of the intra- and interlayer interactions.

Full structural studies of $\mathrm{Cu}_{2}(\mathrm{OH})_{3}(A)$ using single-crystal and powder X-ray diffraction have been reported in a number of cases $\left[A=\mathrm{NO}_{2}{ }^{-}\right.$(Schmidt et al., 1993), $\mathrm{NO}_{3}{ }^{-}$(Effenberger, 1983; Guillou et al., 1994), $\mathrm{Cl}^{-}$(Hawthorne, 1985), $\mathrm{Br}^{-}$ (Oswald et al., 1961) and $\mathrm{CH}_{3} \mathrm{COO}^{-}$(Masciocchi et al., 1997)]. These results, together with EXAFS studies of compounds with $A=\mathrm{CH}_{3} \mathrm{COO}^{-}$and $\mathrm{Br}^{-}$(Jiménez-López et al., 1993), provide evidence for the coordination of $A$ to Cu atoms in the copper hydroxide layers. All reported structures exhibit a $\mathrm{Cu}_{2}(\mathrm{OH})_{3} \mathrm{Cl}$ botallackite-type structure, in which the Cu atoms lie in $4+2(\mathrm{O}+A)$ and $4+1+1(\mathrm{O}+\mathrm{O}+A)$ environments.

In this work, we report the structure of a new inorganicorganic hybrid material $\mathrm{Cu}_{2}(\mathrm{OH})_{3}\left[\mathrm{H}_{2} \mathrm{NC}(=\mathrm{O}) \mathrm{NCN}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, in which cyanoureate ions and water molecules reside between the copper(II) hydroxide layers. The cyanoureate ions coordinate to Cu via the nitrile N atoms. Within the layers, there are three crystallographically distinct Cu atoms, two of which, Cu 2 and Cu 3 , reside on inversion centres at special positions $2 a$ and $2 c$, respectively, while the third, Cu 1 , lies on general position $4 e$ (Fig. 1). Each Cu atom has an elongated octahedral coordination, with four shorter $\mathrm{Cu}-\mathrm{O}$ bonds ( $\sim 2 \AA$ ) and two longer bonds ( $>2.3 \AA$ ), in accordance with the Jahn-Teller distortion of Cu in a +2 oxidation state (Table 1). In the cases of atoms Cu 1 and Cu 2 , the longer bonds are to atom N 3 , and for Cu 3 , to atom O 3 . Each O atom within the layer (O1, O2 and O 3 ) is coordinated to three Cu atoms and a H atom. All the H atoms in the structure were located in difference Fourier maps. The copper hydroxide layers lie parallel to the $b c$ plane and stack along the $a$ axis in an $\ldots A A \ldots$ fashion. The $\mathrm{Cu}^{\text {II }}$ ions within the layers form a triangular array (Fig. 2), with the shortest $\mathrm{Cu} \cdots \mathrm{Cu}$ distances in the range 3.010 (3)-3.164 (3) $\AA$, comparable with those found in other $\mathrm{Cu}_{2}(\mathrm{OH})_{3} A$ compounds

Figure 2
A view along the $a$ axis of the inorganic layer, showing the triangular array of $\mathrm{Cu} 1, \mathrm{Cu} 2$ and Cu 3 atoms within the $\mathrm{Cu}_{2} \mathrm{O}_{3}$ layers. Key: small white spheres are O atoms and small grey spheres are N 3 atoms. The remaining atoms of the cyanoureate ions, together with the hydroxide H atoms, have been omitted.
known to exhibit intralayer magnetic interactions (JiménezLópez et al., 1993).

The interlayer space contains cyanoureate ions, formed by the hydrolysis of dicyanamide anions, viz. $\left[\mathrm{N}(\mathrm{CN})_{2}\right]^{-}$, under basic conditions, together with water molecules. The bond lengths and angles within the cyanourea moiety are in good agreement with those observed for the anions in $\mathrm{Ag}^{+}\left[\mathrm{H}_{2} \mathrm{NC}(=\mathrm{O}) \mathrm{NCN}\right]^{-}$(Britton, 1987) and $\mathrm{NH}_{4}^{+}\left[\mathrm{H}_{2} \mathrm{~N}-\right.$ $\mathrm{C}(=\mathrm{O}) \mathrm{NCN}]^{-}$(Lotsch \& Schnick, 2004). The cyanoureate ion is almost planar, with a cis arrangement of the N3/C2/N2 and O 4 groups. This conformation enables atom O 4 of the $\mathrm{C} 1=\mathrm{O} 4$ carbonyl group to form a hydrogen bond with the $\mathrm{O} 1-\mathrm{H} 1$ hydroxide group of the layer, as well as with the interlayer water molecules $\mathrm{H}_{2} \mathrm{O} 5$ and $\mathrm{H}_{2} \mathrm{O} 6$ (Table 2 and Fig. 3). The other hydroxide groups, O 2 H 2 and O 3 H 3 , also form hydrogen bonds with water molecules $\mathrm{H}_{2} \mathrm{O} 6$ and $\mathrm{H}_{2} \mathrm{O} 5$, respectively, which in turn interact with each other. Hydrogenbonding interactions between the amide $\mathrm{N}_{1} \mathrm{H}_{2}$ group and the central N 2 atom of cyanoureate anions associated with adjacent layers serve to hold the layers together.

To the best of our knowledge, $\mathrm{Cu}_{2}(\mathrm{OH})_{3}\left[\mathrm{H}_{2} \mathrm{NC}(=\mathrm{O})\right.$ $\mathrm{NCN}] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ is the first example of a layered solid in which the cyanoureate ion acts a ligand coordinating to a metal centre. Compounds are known in which the cyanoureate ion links metal atoms into dimers, e.g. in $\left[\mathrm{Cu}_{2}\left\{\mathrm{NCNC}(=\mathrm{O}) \mathrm{NH}_{2}\right\}\right.$ $(\mathrm{R} 3 \mathrm{Bm})]\left(\mathrm{ClO}_{4}\right)_{3} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ (where R 3 Bm is an $m$-xylyl-linked cryptand; Escuer et al., 2004), and chains, e.g. in $\mathrm{Ag}^{+}\left[\mathrm{H}_{2} \mathrm{NC}(=\mathrm{O}) \mathrm{NCN}\right]^{-}$(Britton, 1987). Interestingly, coordination to the Cu atoms occurs through atom N 3 of the nitrile group rather than through atom N 2 , which formally carries the negative charge of the ion. In this respect, the behaviour of the

Figure 3
A view along the $b$ axis, showing the $\ldots A A \ldots$ stacking of the copper hydroxide layers. Hydrogen-bonding interactions between the O1H, O2H and O 3 H hydroxide groups, the $\mathrm{H}_{2} \mathrm{O} 5$ and $\mathrm{H}_{2} \mathrm{O} 6$ water molecules, and the $\mathrm{O} 4=\mathrm{C} 1$ group, together with those involving the $\mathrm{N}_{1} \mathrm{H}_{2}$ and N 2 groups of adjacent cyanoureate ions, are shown as dotted lines. Key: large black spheres are Cu atoms, small white spheres are O atoms, small dark-grey spheres are N atoms, small black spheres are C atoms and very small white spheres are H atoms. The symmetry codes are as in Table 2.
ligand resembles that of the dicyanamide ion (Batten \& Murray, 2003), particularly as observed in the two polymorphs of silver dicyanamide (Britton \& Chow, 1977; Britton, 1990).

## Experimental

Single crystals of the title compound, in the form of blue-green blocks, were obtained from the hydrolysis of $\left[\mathrm{N}(\mathrm{CN})_{2}\right]^{-}$ions under alkaline conditions. Copper(I) dicyanamide ( 0.10 g ) (Wang et al., 1990) was dissolved in an aqueous ammonia solution ( $35 \%, 15 \mathrm{ml}$ ) containing 10 drops of hydrazine. This formed a deep-blue solution which, over the course of 10 min , turned through green to orange. After a few days, the solution had returned to the deep-blue colour and after 10 months a small number of crystals suitable for singlecrystal X-ray diffraction had grown. Intense bands were observed in the IR spectrum recorded in Spectrosol over the range 4000$1300 \mathrm{~cm}^{-1}: 3467,3354,3312,3220(\nu \mathrm{~N}-\mathrm{H}, \mathrm{O}-\mathrm{H}) ; 2174,2137$ ( $v$ $\mathrm{C} \equiv \mathrm{N}) ; 1657$, $1650(\nu \mathrm{C}-\mathrm{O}) ; 1535,1529\left(\delta \mathrm{NH}_{2}\right) ; 1412(\nu \mathrm{C}-\mathrm{N})$.

## Refinement

$R[F>2 \sigma(F)]=0.031$
$w R(F)=0.025$
$S=1.11$
1731 reflections
151 parameters 9 restraints

H atoms treated by a mixture of independent and constrained refinement
$\Delta \rho_{\max }=0.96 \mathrm{e}^{\AA^{-3}}$
$\Delta \rho_{\text {min }}=-0.81 \mathrm{e}^{-3}$

All H atoms were located in difference Fourier maps and restrained to ride on their parent atoms $[\mathrm{O}-\mathrm{H}=\mathrm{N}-\mathrm{H}=0.85$ (1) $\AA]$. For the H atoms attached to framework atoms O1-O3, the fractional coordinates and isotropic displacement parameters were refined. For the remaining H atoms on water molecules $\mathrm{H}_{2} \mathrm{O} 5$ and $\mathrm{H}_{2} \mathrm{O} 6$ and
amide fragment $-\mathrm{N}_{1} \mathrm{H}_{2}$, the fractional coordinates were refined, with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{O})$ and $1.2 U_{\text {eq }}(\mathrm{N})$, respectively.

Data collection: CrysAlis CCD (Oxford Diffraction, 2006); cell refinement: CrysAlis RED (Oxford Diffraction, 2006); data reduction: CrysAlis RED; program(s) used to solve structure: SIR92 (Altomare et al., 1994); program(s) used to refine structure: CRYSTALS (Betteridge et al., 2003); molecular graphics: CAMERON (Watkin et al., 1996); software used to prepare material for publication: CRYSTALS

The authors thank the EPSRC for a grant in support of the purchase of a single-crystal diffractometer and a studentship for EJB.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: EM3026). Services for accessing these data are described at the back of the journal.
