catena-Poly[[tetraaquabis(1H-pyrazole- $\kappa N^{2}$ )nickel(II)] [[diaquabis( $1 H$-pyrazole- $\kappa N^{2}$ )nickel(II)]- $\mu$-benzene-1,2,4,5-tetra-carboxylato- $\left.\kappa^{2} O^{1}: O^{4}\right]$ tetrahydrate $],\left\{\left[\mathrm{Ni}\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\right.$ $\left.\left[\mathrm{Ni}\left(\mathrm{C}_{10} \mathrm{H}_{2} \mathrm{O}_{8}\right)\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$, (I), and poly[[( $\mu_{4^{-}}$ benzene-1,2,4,5-tetracarboxylato- $\kappa^{4} O^{1}: O^{2}: O^{4}: O^{5}$ )octakis $(1 \mathrm{H}$ -pyrazole- $\kappa N^{2}$ ) dicobalt(II)] tetrahydrate], $\left\{\left[\mathrm{Co}_{2}\left(\mathrm{C}_{10} \mathrm{H}_{2} \mathrm{O}_{8}\right)\right.\right.$ $\left.\left.\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{8}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$, (II), are polymeric compounds crystallizing in the space group $P \overline{1}$, with two independent metallic cations and one benzene-1,2,4,5-tetracarboxylate (btc) anion, each lying on symmetry centres. Individual coordination polyhedra are regular and the main differences are in the way the btc anion binds [ $\mu_{2}$ in (I) and $\mu_{4}$ in (II)], promoting a 'chain-like' one-dimensional structure in (I) and a 'sieve-like' two-dimensional motif in (II).

## Comment

The study of one-, two- or three-dimensional molecular systems based on carboxylate-bridged metal centres is attractive not only due to their usually interesting structural characteristics (Eddaoudi et al., 2001) but also for their potential applications, viz. in heterogeneous catalysis, medicine or chemical separation, and, on occasion, due to their eventual electronic and/or magnetic properties (Yaghi et al., 1996; Ait-Haddou et al., 2004).

In the synthesis of these systems, several factors are of relevance, namely the characteristics of the organic ligands, such as bridging capacity, shape, functionality, flexibility, etc. (Tudor et al., 2003; Kooijman et al., 2004), the noncovalent interactions which they might eventually give rise to, viz. hydrogen bonding, $\pi-\pi$ interactions, etc. (Perron et al., 2004), and, obviously, the nature of the metal ion.

The dramatic effect of this latter factor is apparent in the title complexes, $\left[\mathrm{Ni}(\mathrm{pyr})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+} \cdot\left[\mathrm{Ni}(\text { btc })(\text { pyr })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2-}$.$4 \mathrm{H}_{2} \mathrm{O}$ (btc is benzene-1,2,4,5-tetracarboxylate and pyr is pyrazole), (I), and $\mathrm{Co}_{2}(\mathrm{btc})(\mathrm{pyr})_{8} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, (II), where absolute similarity in synthetic procedures, reaction conditions and reactant characteristics (containing closely related, but not identical, metal cations) nevertheless results in different compounds, both at a molecular and at a crystal structure level.

$-4 n \mathrm{H}_{2} \mathrm{O}$
(I)

(II)

Figs. 1 and 2 show molecular views of (I) and (II), respectively. Tables 1 and 3, in turn, give some selected coordination parameters, and Tables 2 and 4 provide the hydrogen-bonding interactions. Even though both structures are polymeric and crystallize in the triclinic space group $P \overline{1}$, with two octahedral metal centres and one btc ligand occupying special positions on non-equivalent symmetry centres, this is basically the only common feature they share.

Compound (I) is ionic, with two well differentiated centrosymmetric substructures, viz. $\left\{\left[\mathrm{Ni}(\mathrm{btc})(\mathrm{pyr})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2-}\right\}_{n}$ and $n\left[\mathrm{Ni}(\mathrm{pyr})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$. The Ni centre in each of these ionic units displays a rather regular octahedral environment, with mean coordination distances $\mathrm{Ni}-\mathrm{O}=2.085$ (3) and 2.068 (9) $\AA$, and $\mathrm{Ni}-\mathrm{N}=2.070$ (3) and 2.068 (3) $\AA$, and extreme values for the cis coordination angles of $90 \pm 3.82$ (8) and $90 \pm 2.62(10)^{\circ}$ for atoms Ni1 and Ni2, respectively.

In (II), instead, both Co centres present one and the same $\mathrm{Co}\left(\mathrm{O}_{\mathrm{btc}}\right)_{2}\left(\mathrm{~N}_{\mathrm{pyr}}\right)_{4}$ coordination but with comparable regularity

Figure 1
A molecular view of (I), showing the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level and H atoms are shown as small spheres of arbitrary radii. The asymmetric unit is shown in bold. [Symmetry codes: (i) $-x, 1-y, 2-z$; (ii) $-x+1,-y,-z+1$; (iii) $-x,-y+1$, $-z+1$.]
in the mean coordination distances of $\mathrm{Co}-\mathrm{O}=2.133$ (3) and 2.070 (2) $\AA$, and $\mathrm{Co}-\mathrm{N}=2.070$ (3) and 2.120 (7) $\AA$, and extreme values for the cis coordination angles of $90 \pm 4.87$ (9) and $90 \pm 2.03(9)^{\circ}$ for atoms Co 1 and Co2, respectively.

Figure 2
A molecular view of (II), showing the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level and H atoms are shown as small spheres of arbitrary radii. The asymmetric unit is shown in bold. [Symmetry codes: (i) $-x, 1-y, 2-z$; (ii) $-x,-y+2$, $-z+1$; (iii) $-x,-y+1,-z+1$.]

(a)

(b)

Figure 3
Packing view of (I), projected down [100]*. (a) At height $x=0.00$, showing the (covalent) anionic chains running along [001], and (b) at height $x=\frac{1}{2}$, showing the (hydrogen-bonded) cationic chains running along [010].

Packing view of (I), projected down [001]*. (a) At height $z=0.00$, showing a cross-section of the (covalent) anionic chains running along [001] (out of the figure), and (b) at height $z=\frac{1}{2}$, showing the (hydrogenbonded) cationic chains running along [010], in between the former chains.

As already stated, the btc anion in both structures lies on a centre of symmetry and, even though it acts as the bridging agent in both cases, it does so in two quite different ways, binding in a $\mu_{2}$-bidentate fashion in Ni compound (I) and in a $\mu_{4}$-tetradentate way in Co compound (II). This results in dramatic differences in both structural dimensionality and packing behaviour.

In (I), the simple bridging of the $\left[\mathrm{Ni}(\mathrm{pyr})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ groups via the $\mathrm{btc}^{4-}$ anions generates negatively charged chains parallel to [001] containing only one of the two independent Ni atoms, viz. Ni1 (Fig. 3a). Atom Ni2 is involved in the formation of isolated $\left[\mathrm{Ni}(\mathrm{pyr})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ cationic groups which form hydrogen-bonded chains perpendicular to the first set, which balance the charges (see discussion below and Fig. 3b).

The larger connectivity of the anion in (II) determines a two-dimensional array with a square grid motif (Fig. 2) presenting the $\mathrm{btc}^{4-}$ ligands at the corners, interconnecting the two non-equivalent $\left[\mathrm{Co}(\mathrm{pyr})_{4}\right]^{2+}$ units located at the edge centres, in a process which involves both atoms Co 1 and Co 2 . The result, presented in Fig. 5, is a neutral tightly bound twodimensional structure in the form of a 'sieve'.

The way in which the polymeric entities interact with each other in each structure is also different, though mediated in both cases by an extremely complex hydrogen-bonding scheme where all the available donors are active [ten water $\mathrm{O}-\mathrm{H}$ groups, two pyr $\mathrm{N}-\mathrm{H}$ groups plus two nonconventional

Figure 5
Packing view of (II), projected down [100]*, showing (in bold) the 'grid structure' generated by $\mathrm{Co}^{\text {II }}$ cations and btc anions.

Figure 6
Packing view of (II), projected down [010]*, showing the water-mediated hydrogen-bond interaction between two-dimensional 'grid structures' (in bold).
pyr $\mathrm{C}-\mathrm{H}$ groups in (I), and four water $\mathrm{O}-\mathrm{H}$ groups plus four pyr $\mathrm{N}-\mathrm{H}$ groups in (II); Tables 3 and 4]. The only exception is atom $\mathrm{H} 5 W A$ in (I), which does not have any possible acceptor to interact with (see Refinement). The remaining H atoms on atoms O4W and O5W interlink the isolated cationic units having atoms Ni 2 as their centres, to define hydrogen-bonded chains running along $b$ (Fig. 3b), almost perpendicular to the covalent chains which run along $c$, but shifted half a unit-cell translation along $a$, so that they do not intersect. Figs. 4(a) and $4(b)$ show views along the $c$ direction, with a $c / 2$ shift in the vertical direction, suggesting the way in which the voids between covalent chains (Fig. 4a) are 'filled' by the hydrogenbonded Ni2 chains (Fig. 4b). Hydrogen bonding between the two types of ionic chains stabilizes the structure.

The interplanar interactions in (II) are simpler and are mediated by two solvent water molecules basically interacting with the carboxylate O atoms (Fig. 6). There is, in addition, a $\pi-\pi$ bond involving one of the pyr rings $[C g \cdots C g(1-x,-y$, $1-z)=3.74 \AA$ and slippage $=26.66^{\circ} ; C g$ is the centroid of the N15/N25/C15/C25/C35 ring].

A survey of the 2009 version of the Cambridge Structural Database (CSD; Allen, 2002) shows that no structures have been published previously containing both the btc anion and the pyr ligand. There are, however, quite a few with the closely related imidazole (imid) group, differing from pyr in that the
two N atoms are not nearest neighbours (positions 1 and 2 in the ring) but next-nearest (positions 1 and 3). In particular, CSD refcode OJOTEM (Cheng et al., 2003), (III), is almost isostructural with (I) in that it presents the equivalent $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{btc}\right)\left(\mathrm{L}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]_{n}\right.$ covalent anionic chain counterbalanced by a perpendicular non-intersecting hydrogenbonded chain made up of water molecules and $\left[\mathrm{Ni}(L)_{n}\left(\mathrm{H}_{2} \mathrm{O}\right)_{m}\right]^{2+}$ cations, the differences being that in OJOTEM $L=\operatorname{imid}, m=2$ and $n=4$, while in (I) $L=$ pyr, $m=4$ and $n=2$.

This 'quasi-isostructurality' between complexes (I) and (III), with an almost identical disposition of equivalent groups, ends at and does not include the position of the noncoordinated 'second' N atom ( N 22 ) in the five-membered ring. In (I), it occupies site 2, vicinal to the coordinated atom N21 at site 1, a position which forces its H atom (H22) to point inwards within the chain (see Fig. 1), and thus it forms intrachain rather than interchain hydrogen bonds. Its counterpart in OJOTEM, instead, occupies position 3 in the five-membered ring (next-nearest neighbour to the coordinated N atom, the position occupied by atom C12 in Fig. 1), and thus points outwards from the chain in a suitable orientation to act as a donor for strong interchain bonds, which serve to build up hydrogen-bonded two-dimensional structures instead of the basically isolated chains found in (I).

A similar situation arises in (II) where, due to their inwardfacing orientation, three out of the four possible $\mathrm{N}-\mathrm{H}$ groups are forced to make intraplanar hydrogen bonds (Table 4 and Fig. 6) and only the fourth ( $\mathrm{N} 25-\mathrm{H} 25$ ) is involved in the interplanar linkage, via a hydrogen-bonding interaction mediated by atom O1W.

As a final curiosity resulting from this CSD search, it can be mentioned that the $\left[\mathrm{Ni}(\mathrm{pyr})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ group in (I) has been reported only once before, its only appearance being in a copper complex (CSD refcode UFIDUI; Wang et al., 2001).

## Experimental

An aqueous solution ( 30 ml ) containing Ni (acetate) $)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.2985 \mathrm{~g})$ or $\mathrm{Co}(\text { acetate })_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.2988 \mathrm{~g})$ for (I) and (II), respectively, was added slowly to an aqueous solution $(150 \mathrm{ml})$ containing benzene-$1,2,4,5$-tetracarboxylic acid ( 0.1525 g ) and $\mathrm{NaOH}(0.0903 \mathrm{~g})$. The reaction mixture was heated under reflux for 10 min . An ethanolic solution ( 30 ml ) of pyrazole ( 0.2055 g ) was added and the resulting solution was maintained under reflux for 4 h . Single crystals suitable for X-ray crystallography were grown from the solution by slow evaporation at room temperature.

C-bound H atoms were constrained geometrically and allowed to ride, with $\mathrm{C}-\mathrm{H}=0.93-0.97 \AA$. O-bound H atoms were initially found in a difference electron-density map and refined with restrained $\mathrm{O}-\mathrm{H}[0.85(1) \AA]$ and $\mathrm{H} \cdots \mathrm{H}[1.30$ (2) $\AA$ ] distances until convergence, and then constrained, riding on the host O atoms in the final cycles. In all cases, $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}$ (parent).

For both compounds, data collection: SMART-NT (Bruker, 2001); cell refinement: SAINT-NT (Bruker, 2002); data reduction: SAINT$N T$; program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL97 (Sheldrick,
2008); molecular graphics: SHELXTL-NT (Sheldrick, 2008); software used to prepare material for publication: SHELXTL-NT and PLATON (Spek, 2009).

The authors acknowledge the Spanish Research Council (CSIC) for providing a free-of-charge licence to the CSD system. We are also grateful for funding by FONDECYT (project No. 1071061).

Supplementary data for this paper are available from the IUCr electronic archives (Reference: EM3027). Services for accessing these data are described at the back of the journal.
