The sodium salt of [immucillin- $\left.\mathrm{A}-\mathrm{CO}_{2} \mathrm{H}\right]^{-}$(Imm-A), namely catena-poly[[[triaquadisodium(I)]((%5Cmu)-aqua) $[\mu-(1 S)-N$-carboxyl-ato-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-d-ribitol] [triaquadisodium(I)][ $\mu$-(1S)- $N$-carboxylato-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-d-ribitol]] tetrahydrate $],\left\{\left[\mathrm{Na}_{2}\left(\mathrm{C}_{12}{ }^{-}\right.\right.\right.$ $\left.\left.\left.\mathrm{H}_{13} \mathrm{~N}_{4} \mathrm{O}_{6}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{7}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$, (I), forms a polymeric chain via $\mathrm{Na}^{+}-\mathrm{O}$ interactions involving the carboxylate and keto O atoms of two independent Imm-A molecules. Extensive $\mathrm{N}, \mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding utilizing all water H atoms, including four waters of crystallization, provides crystal packing. The structural definition of this novel compound was made possible through the use of synchrotron radiation utilizing a minute fragment (volume $\sim 2.4 \times 10^{-5} \mathrm{~mm}^{-3}$ ) on a beamline optimized for protein data collection. A summary of intra-ring conformations for immucillin structures indicates considerable flexibility while retaining similar intra-ring orientations.

## Comment

The title compound, (I), was prepared as part of continuing studies of the so-called 'immucillin' family of compounds which are potent aza-C-nucleoside inhibitors of purine nucleoside phosphorylase (Evans et al., 2003). The immucillin compounds do not usually form adequate-quality crystals, and only adducts protonated on the aza-ribitol sugar (N1) positions have been reported (MILMAV: Federov et al., 2001; MEFZOM: Evans et al., 2000) (alphabetic codes used herein are those used in the Cambridge Structural Database, 2009). A related compound, with oxygen replacing NH in the saturated five-membered ring, is VOVJIZ (Otter et al., 1992), while
compound VILHON (Ikegami et al., 1990) has been reassigned as a related $6^{\prime}$-amino compound by Otter et al. (1992). Some of these compounds have been successfully defined 'in action' as inhibitors in sites within the enzymes (e.g. MT-Imm-A; Singh et al., 2004). The size of the crystal fragment used here meant that both the superb power and resolution of synchrotron radiation were essential even when used in the less than optimum settings at the end of a protein data collection. We are thus able to present the first anionic derivative of this family.

(I)

The asymmetric unit contents of the title compound, (I), are shown in Fig. 1; the polymer linking bonds ( $\mathrm{Na} 1^{*}-\mathrm{O} 16$, $\left.\mathrm{Na} 1-\mathrm{O} 16^{*}\right)$ are shown at the top and bottom of the figure (see also Fig. 2 and the scheme above). The two independent $\mathrm{Imm}-\mathrm{A}-\mathrm{CO}_{2}{ }^{-}$molecules, which are label-related by adding 10 to the number of the first (i.e. N 1 and N 11 ), are almost superimposable. The absolute configurations at $\mathrm{C}^{\prime}(S), \mathrm{C}^{\prime}$ $(S), \mathrm{C}^{\prime}(R)$ and $\mathrm{C}^{\prime}(R)$ indicated by a Flack parameter of 0.0 (3) agree with the stereochemistry known from the synthesis. There is a slight difference in tilt angle, $\sim 10^{\circ}$, between the two rings (see the dihedral angles around $\mathrm{C1}^{\prime}-\mathrm{C} 9$ and $\mathrm{C} 11^{\prime}-\mathrm{C} 19$ in Table 1), and ring comparisons (Spek, 2009) give r.m.s. bond and angle fits of $0.016 \AA$ and $1.25^{\circ}$, respectively. The 1,9-deazaadenin-9-yl nine-membered rings (e.g. $\mathrm{N} 1 / \mathrm{C} 2 / \mathrm{N} 3 / \mathrm{C} 4 / \mathrm{C} 9 / \mathrm{C} 8 / \mathrm{N} 7 / \mathrm{C} 5 / \mathrm{C} 6$ ) are made up of two rigidly planar five- and six-membered rings, with the planes at an average angle of $1.8(3)^{\circ}$ with respect to each other. The five-membered (imino-ribitol) rings (e.g. $\left.\mathrm{N} 1^{\prime} / \mathrm{C} 1^{\prime}-\mathrm{C} 4^{\prime}\right)$ are puckered on C2' and C3 $3^{\prime}$ [Cremer \& Pople (1975) parameters $Q(2)=0.342(6) \AA$ and $\left.\varphi(2)=272.3(9)^{\circ}\right]$ in molecule 1 and twisted on $\mathrm{C} 12^{\prime}-\mathrm{C}_{1}^{\prime}[Q(2)=0.307(6) \AA$ and $\varphi(2)=$ $\left.268.2(10)^{\circ}\right]$ in the other. Such variations are normal, as shown by the pyrrolidine-1-carboxylate adduct FISNUR (ZukermanSchpector et al., 2005) which also twists along $\mathrm{C}^{\prime}-\mathrm{C}^{\prime}[Q(2)=$ $0.426 \AA$ and $\left.\varphi(2)=266.4(3)^{\circ}\right]$.

Figure 1
Diagram of the asymmetric unit and two extra atoms of (I), shown with $50 \%$ displacement ellipsoids (Farrugia, 1997). Atoms Na1* (at $x-1$, $y-1, z$ ) and O16* (at $x+1, y+1, z$ ) are included and linked by threeline bonds to show the polymeric linkages. H atoms have arbitrary radii. Identified hydrogen bonds within the asymmetric unit are shown as dashed lines. The H atoms on water atom O 10 W were not located.

For completeness, we note that other pyrimidin-4-one structures have been reported: FOYWIZ (Girgis et al., 1987) and QINBOE (Jukic et al., 2000); the former has (fortuitously) similar relative orientations of the two rings to molecule 1 here.

One of the $\mathrm{Imm}-\mathrm{A}-\mathrm{CO}_{2}{ }^{-}$molecules provides a bridging oxygen (O6) to the two independent cations, while the other bonds to only Na 2 through carboxylate atom $\mathrm{O} 7 b^{\prime}$ (Fig. 1). The Na cations are further bridged by one water molecule ( $\mathrm{O} 2 W$ ) and both have the usual approximate octahedral binding stereochemistry, with variation in $\mathrm{Na}-\mathrm{O}$ distances depending on the trans donor atoms. Finally, the packing cohesion is provided by extensive hydrogen bonds involving all the waters of crystallization, the aqua molecules and the Imm-A- $\mathrm{CO}_{2}{ }^{-} \mathrm{N}$-bound H atoms as donors (Table 2, and scheme). Overall, the structure can be described as a polymeric chain parallel to the ( $1 \overline{1} 1$ ) plane crosslinked by hydrogen bonds to the water molecules that lie between the chains (Fig. 2).

It is of interest to compare the relative conformations of the two independent $\mathrm{Imm}-\mathrm{A}-\mathrm{CO}_{2}^{-}$molecules here with the previously reported (free) Imm-H cationic molecules and Imm-H as found bound in a human purine nucleoside phosphorylase mutant (Table 3). There is quite a wide variation of relative conformations of the ten-membered 9-deaza-adenin-9-yl and the 4 -aza-ribitol rings with respect to the linking bond (e.g. $\mathrm{C} 1-\mathrm{C} 9^{\prime}$ ), with the two independent molecules here being closely related both in intra-ring orientations and in the 4 -aza-ribitol ring descriptions. This is rather remarkable given the variation that might be expected in the strongly hydrogen-bonded network and with each molecule

Figure 2
Packing diagram of the cell of (I) (Bruno et al., 2002), viewed approximately down the $c$ axis. Representative atom labels are given (see Comment and Table 2) and H atoms have been omitted for clarity. Hydrogen bonds are shown as dashed lines. (Key in the electronic version of the paper: N , blue sticks; Na, purple balls; O , red sticks; C , grey wires.)
involved in different interactions with the cations. Agreement between the two free $\mathrm{Imm}-\mathrm{H}$ studies (entries 4 and 6 in Table 3) is also notable. It is also apparent that the proteinbound molecule (entry 5) has been twisted about the link bond in response to close interactions, but still retains a similar intraplanar angle (between the two rings) to that in the free ligand structures. The linking factor in these determinations is that the variable conformations retain a similar intraplanar angle with only minor variations in the attachment angles [e.g. $\mathrm{C}^{\prime}-\mathrm{C} 9-\mathrm{C} 8=126.3(5)^{\circ}$ and $\mathrm{C} 11^{\prime}-\mathrm{C} 19-\mathrm{C} 18=129.1(5)^{\circ}$ here, compared with $130.2^{\circ}$ in the bound molecule (Murkin et al., 2007)].

## Experimental

The title compound (immucillin- $\mathrm{A}-\mathrm{CO}_{2} \mathrm{H}$ ) was made by incubation of the Imm-A-HCl salt ( $50 \mathrm{mg}, 0.165 \mathrm{mmol}$ ) (Evans et al., 2003) dissolved in water ( 2 ml ). The compound was deprotonated with sodium hydroxide ( $0.165 \mathrm{mmol}, 6.6 \mathrm{mg}$ ) dissolved in water ( $100 \mu \mathrm{l}$ ), which caused precipitation, but the addition of more sodium hydroxide ( $0.165 \mathrm{mmol}, 6.6 \mathrm{mg}$ ) dissolved in water ( $100 \mu \mathrm{l}$ ) caused the compound to redissolve. The aqueous mixture was left open to the atmosphere to allow evaporation of the solvent (and absorption of $\mathrm{CO}_{2}$ ) and for crystallization. The described material crystallized after a week.

2357 measured reflections
2357 independent reflections

## Refinement

$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.035$
$w R\left(F^{2}\right)=0.092$
$S=1.07$
2357 reflections
360 parameters
27 restraints
$R_{\text {int }}=0.034$
$\theta_{\text {max }}=25.5^{\circ}$

H atoms treated by a mixture of independent and constrained refinement
$\Delta \rho_{\text {max }}=0.22 \mathrm{e}_{\AA_{\circ}^{-3}}$
$\Delta \rho_{\min }=-0.21 \mathrm{e}^{-3}$
Absolute structure: Flack (1983), with 1161 Friedel pairs Flack parameter: 0.0 (3)

One low-angle reflection ( $\overline{1} 10$ ) and eight high-angle reflections $\left(\Delta\left(F^{2}\right) /\right.$ e.s.d. $\left.>3.8\right)$ were omitted. A total of 44 non-H atoms were refined with isotropic displacement parameters (some being unstable to anisotropic refinement) thereby improving the data/parameter value. The number of Friedel pairs was 1161. All H atoms were constrained, with $U_{\text {iso }}$ values of 1.2 times the $U_{\text {eq }}$ of the parent atom for C, N and hydroxy O atoms, and with $U_{\text {iso }}$ values of 1.2 times the $U_{\text {eq }}$ of the parent atom for water O atoms. Most water H atoms were located on difference Fourier maps; other water H atoms were positioned from stereochemical considerations and confirmed by improved agreement factors and Fourier maps. The O10W water H atoms could not be resolved from difference Fourier maps and their placement lead to unacceptably close contacts with other water H atoms ( $<1.5 \AA$ ); they were thus excluded from the final refinement. In the final refinements, all water $\mathrm{O}-\mathrm{H}$ distances were constrained to 0.82 (3) $\AA$, with a minimum $\mathrm{H} \cdots \mathrm{H}$ distance of 1.35 (3) $\AA$. In the final model, there are some close water $\mathrm{H} \cdots \mathrm{H}$ distances reflecting the model and data limitations. All other H atoms were geometrically constrained (riding model) to $\mathrm{C}-\mathrm{H}, \mathrm{N}-\mathrm{H}$ and $\mathrm{O}-\mathrm{H}$ bond lengths of $0.99,0.88$ and $0.84 \AA$, respectively.

Data collection: DENZO (Otwinowski \& Minor, 1997); cell refinement: DENZO; data reduction: DENZO and SCALEPACK (Otwinowski \& Minor, 1997); program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL97 (Sheldrick, 2008); molecular graphics: ORTEP in WinGX (Farrugia, 1997) and PLATON (Spek, 2009); software used to prepare material for publication: SHELXL97, PLATON and Mercury (Bruno et al., 2002).
