Three potassium edta (edta is ethylenediaminetetraacetic acid, $\mathrm{H}_{4} Y$ ) salts which have different degrees of ionization of the edta anion, namely dipotassium 2-(\{2-[bis(carboxyl-atomethyl)azaniumyl]ethyl\}(carboxylatomethyl)azaniumyl)acetate dihydrate, $2 \mathrm{~K}^{+} \cdot \mathrm{C}_{10} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{8}{ }^{2-} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, (I), tripotassium 2,2'-(\{2-[bis(carboxylatomethyl)amino]ethyl\}ammonio)diacetate dihydrate, $3 \mathrm{~K}^{+} \cdot \mathrm{C}_{10} \mathrm{H}_{13} \mathrm{~N}_{2} \mathrm{O}_{8}{ }^{3-} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, (II), and tetrapotassium $\quad 2,2^{\prime}, 2^{\prime \prime}, 2^{\prime \prime \prime}$-(ethane-1,2-diyldinitrilo)tetraacetate 3.92-hydrate, $4 \mathrm{~K}^{+} \cdot \mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}{ }^{4-} \cdot 3.92 \mathrm{H}_{2} \mathrm{O}$, (III), were obtained in crystalline form from water solutions after mixing edta with potassium hydroxide in different molar ratios. In (II), a new mode of coordination of the edta anion to the metal is observed. The $\mathrm{H}^{3-}$ anion contains one deprotonated N atom coordinated to $\mathrm{K}^{+}$and the second N atom is involved in intramolecular bifurcated $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds. The overall conformation of the $\mathrm{H} Y^{3-}$ anions is very similar to that of the $Y^{4-}$ anions in (III), although a slightly different spatial arrangement of the $-\mathrm{CH}_{2} \mathrm{COO}^{-}$groups in relation to (III) is observed, whereas the $\mathrm{H}_{2} Y^{2-}$ anions in (I) adopt a distinctly different geometry. The preferred synclinal conformation of the $-\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{~N}-$ moiety was found for all edta anions. In all three crystals, the anions and water molecules are arranged in three-dimensional networks linked via $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ [and $\mathrm{N}-$ $\mathrm{H} \cdots \mathrm{O}$ in (I) and (II)] hydrogen bonds. K $\cdots \mathrm{O}$ interactions also contribute to the three-dimensional polymeric architecture of the salts.

## Comment

In the crystallographic literature, the most common form of edta [edta is ethylenediaminetetraacetic acid $\left(\mathrm{H}_{4} Y\right)$ or $2,2^{\prime}, 2^{\prime \prime}, 2^{\prime \prime \prime}$-(ethane-1,2-diyldinitrilo)tetraacetic acid] is the tetraanion, viz. $Y^{4-}$. Another anionic form of edta is $\mathrm{H}_{2} Y^{2-}$ reported in salts of $\mathrm{Na}, \mathrm{K}$ and Rb (Font-Bardia et al., 1993; Cotrait, 1969, 1970). Therefore, it seemed an attractive idea to obtain and structurally characterize crystalline potassium edta
salts, especially the tripotassium edta salt, (II), which is an example of a new coordination mode of this edta anion to a metal centre, and tetrapotassium edta, (III), which is analogous to the $\mathrm{Na}_{4} Y \cdot 5 \mathrm{H}_{2} \mathrm{O}$ salt (Font-Bardia et al., 1993). Potassium edta salts are used as anticoagulants for haematologic examinations of human and animal blood (Balakrishnan et al., 2006; Hekimsoy et al., 2004; Vatn et al., 2000; Olsen et al., 2001; Sanchez-Migallon Guzman et al., 2008). In addition, potassium edta salts have applications as chelating agents in cosmetics (Lanigan \& Yamarik, 2002).

(II)

The strategies for preparing the potassium edta salts reported here, viz. (I), (II) and (III), result from the occurrence of acid-base equilibria in aqueous solution between edta anions in different ionization states. The acidity of the solutions plays a crucial role in controlling the particular forms of the edta anions, i.e. $\mathrm{H}_{3} Y^{-}, \mathrm{H}_{2} Y^{2-}$, $\mathrm{H} Y^{3-}$ and $Y^{4-}$ (Harris, 1999), as follows. The $\mathrm{H}_{3} Y^{-}$anion is dominant in aqueous solutions at pH values of around 2.5 and its conjugate acid, i.e. the $\mathrm{H}_{4} Y$ zwitterion, is present at $\mathrm{pH} \sim 1.8$. In the pH range 2.7-6.1 $\left(\mathrm{p} K_{a}\left\{\mathrm{H}_{2} Y^{2-}\right\}=2.69 ; \mathrm{p} K_{a}\left\{\mathrm{H} Y^{3-}\right\}=6.13\right)$ the equilibrium shifts towards the $\mathrm{H}_{2} Y^{2-}$ ion. The $\mathrm{H} Y^{3-}$ ion dominates in aqueous solutions in the pH range 6.1-10.4 $\left(\mathrm{p} K_{a}\left\{Y^{4-}\right\}=\right.$ 10.37), whereas the $Y^{4-}$ anion dominates at pH above 10.4.

In contrast to the coordination modes in salts (I), (II), (III), in the majority of compounds that contain edta anions and potassium cations the usual coordination of edta to $\mathrm{K}^{+}$is via one carboxylate group in a monodentate or bidentate way. The literature provides many examples of such compounds, among which the most typical include: the acetate O atom acting as a linker between two metal atoms, e.g. between two $\mathrm{K}^{+}$cations, as in $\mathrm{K}_{4}\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left[\mathrm{Co}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\right]_{2}\left[\mathrm{Mo}_{8} \mathrm{O}_{26}\right]$-$6 \mathrm{H}_{2} \mathrm{O}$ (Lee et al., 2002); or between one $\mathrm{K}^{+}$cation and another metal such as Fe , Sb or Mo (Solans et al., 1984; Ilyukhin \& Petrosyants, 2001; Kneale \& Geddes, 1975); or between one $\mathrm{K}^{+}$cation and a lanthanoid cation, as in $\mathrm{K}\left[\mathrm{Ho}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\right.$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Sakagami et al., 1999). Furthermore, the carboxylate O atom of edta can bridge three metal atoms, as in the following examples: three $\mathrm{K}^{+}$cations, as in $\mathrm{K}_{2}\left[\mathrm{Ga}\left(\mathrm{C}_{10} \mathrm{H}_{12}{ }^{-}\right.\right.$ $\left.\left.\mathrm{N}_{2} \mathrm{O}_{8}\right)(\mathrm{OH})\right] \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (Ilyukhin \& Petrosyants, 2001); two $\mathrm{K}^{+}$
cations and another cation such as a lanthanoid, as in $\mathrm{K}\left[\mathrm{Yb}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot 5 \mathrm{H}_{2} \mathrm{O}$ (Sakagami et al., 1997); or one $\mathrm{K}^{+}$cation and two transition metal centres, as in $\mathrm{K}\left[\mathrm{Mo}_{2}\left(\mathrm{C}_{12} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{O}_{10}\right)(\mathrm{OH})_{2}\right]$ (Kneale \& Geddes, 1975).

The present paper reports the structures of three potassium edta salts, $\mathrm{K}_{2}\left[\mathrm{H}_{2} Y\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, (I), $\mathrm{K}_{3}[\mathrm{HY}] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, (II), and $\mathrm{K}_{4}[\mathrm{Y}] \cdot 3.92 \mathrm{H}_{2} \mathrm{O}$, (III) (Fig. 1), and we discuss (II) first because of the fact that it is a unique example of a crystalline salt containing the $\mathrm{H} Y^{3-}$ ion. The geometries of the anions in (I)(III) are described and compared with those in the dirubidium, disodium and tetrasodium edta salts. In addition, the coordination modes of the edta anions to $\mathrm{K}^{+}$ions and the arrangements in the crystal lattices are discussed.

Compound (II) contains one $\mathrm{H} Y^{3-}$ anion, three $\mathrm{K}^{+}$ions and two water molecules of hydration, where the anion is composed of four acetate arms linked to an $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}^{+}$ fragment which adopts a gauche conformation; a novel coordination mode is observed. The $\mathrm{H} Y^{3-}$ ion coordinates to the cation (K1) via one deprotonated N atom (N1) and three acetate O atoms ( $\mathrm{O} 11, \mathrm{O} 21$ and O 32 ), while the second N atom ( N 2 ) is involved in the intramolecular bifurcated N $\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds (Figs. $1 b$ and $2 a$, and Tables 2 and 5). Furthermore, in the seven-coordination polyhedron of K1, two symmetry-related anions are bonded in a bidentate mode (via $\mathrm{O} 32^{\text {vi }}$ and $\mathrm{O} 42^{\text {vi }}$ ) (all symmetry codes are as given in Table 5), forming an eight-membered ring, and

Figure 1
The asymmetric unit of $(a)(\mathrm{I}),(b)(\mathrm{II})$ and $(c)(\mathrm{III})$. For (I) and (II), the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and for (II) the $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ intramolecular hydrogen bonds are shown by thin lines. Displacement ellipsoids are drawn at the $30 \%$ probability level. The disordered atoms (O31C, O32C, O71W and K71) in (III) have been omitted for clarity.
in a monodentate (via $\mathrm{O} 41^{\text {vii }}$ ) mode (Fig. $2 b$ and Table 5). The $\left(\mathrm{OOCCH}_{2}\right)_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}^{+}\left(\mathrm{CH}_{2} \mathrm{COO}\right)_{2}$ unit observed here can also be distinguished in the structure of a fully esterified form of edta with the proton added to one of the N atoms, viz. $\left(\mathrm{C}_{14} \mathrm{H}_{25} \mathrm{~N}_{2} \mathrm{O}_{8}\right)_{2}\left[\mathrm{~W}_{6} \mathrm{Cl}_{14}\right]$ (Adams et al., 1993), where intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds occur, but coordination to the metal atom is not observed. In the case of K 2 , the six-coordination sphere is formed by three $\mathrm{H} Y^{3-}$ anions and one water molecule, O2W (Fig. 2c and Table 5). The anion coordinates to K2 in a bidentate manner via O31 and O32, and is involved in coordination to $K 22^{\text {viii }}$ in a monodentate way via O 22 , as well as interacting with $\mathrm{K} 2^{\mathrm{vi}}$ via O 21 and O 42 (making an 11-membered chelate ring) (Fig. 2d and Table 5). The seven-coordinated K3 atom is surrounded by five edta anions coordinating via O atoms in a monodentate manner and by two water molecules.

In the crystal structure of (II), $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds are present, where water molecules act as donors and carboxylate O atoms act as acceptors (Table 2). Weak

(a)
(c)

Figure 2
hydrogen bonds of the $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ type, where the acetate O atoms participate, also contribute to the structure. The $\mathrm{HY}^{3-}$ anions, water molecules and $\mathrm{K}^{+}$cations are arranged in layers parallel to (100) (Fig. 3a). The interaction between acetate O atoms, water molecules and $\mathrm{K}^{+}$cations results in a threedimensional network.

The asymmetric unit of compound (III) comprises two $Y^{4-}$ anions [denoted (III $a$ ) and (IIIb)], eight potassium cations and water molecules (Fig. 1c). Although the overall conformations of the (III $a$ ) and (IIIb) anions are similar (see Experimental), the spatial arrangements of their acetate arms are not quite the same (Fig. 4). The overall conformations of the anions in (III) are comparable with those of the corresponding $Y^{4-}$ anion in $\mathrm{Na}_{4}$ [edta] $\cdot 5 \mathrm{H}_{2} \mathrm{O}$ (Font-Bardia et al., 1993) and of the $\mathrm{H} Y^{3-}$ ion in (II), although the analogous acetate arms are not arranged in exactly the same manner. Both edta anions in compound (III) chelate $\mathrm{K}^{+}$via six ligating atoms (two N and four carboxylate O atoms), which results in the formation of five-membered rings at both K 1 and K 2 , similar to the

complexes of $Y^{4-}$ ions with many metals; for example, $\mathrm{NH}_{4}\left[\mathrm{Co}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Weakliem \& Hoard, 1959), $\left\{\left[\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Mn}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right) \mathrm{Cu}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$ (Solans et al., 1983) and $\left[\mathrm{Ti}\left(\mathrm{C}_{10} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}_{8}\right)\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Fackler et al., 1985).

Each of the four chelate rings formed by the acetate arms with K1 adopt the $\delta$ conformation ( $\delta \delta \delta \delta$ ) (Corey \& Bailar, 1959; Beattie, 1971; Lee, 1972). In the case of coordination at K2 (coordination number $=8$ ) (Fig. $5 b$ and Table 5), the $\{\mathrm{K} 2$, $\mathrm{O} 11 B, \mathrm{C} 11 B, \mathrm{C} 12 B, \mathrm{~N} 1 B\}$ ring adopts the $\lambda$ conformation, the $\{\mathrm{K} 2, \mathrm{O} 21 B, \mathrm{C} 21 B, \mathrm{C} 22 B, \mathrm{~N} 1 B\}$ and $\{\mathrm{K} 2, \mathrm{O} 32 B, \mathrm{C} 31 B, \mathrm{C} 32 B$, $\mathrm{N} 2 B\}$ rings are in the $\delta$ conformation, whereas the $\{\mathrm{K} 2, \mathrm{O} 42 B$, $\mathrm{C} 41 B, \mathrm{C} 42 B, \mathrm{~N} 2 B\}$ ring adopts a near-envelope conformation; four atoms ( $\mathrm{O} 42 B, \mathrm{C} 41 B, \mathrm{C} 42 B$ and $\mathrm{N} 2 B$ ) are nearly in the same plane (Table 4).

The eight-coordination polyhedron of K1 is made up of two type-(III $a$ ) anions and one water molecule (Fig. $5 a$ and Table 5). The (III $a$ ) anion chelates K1 forming a cage structure and coordinates to $\mathrm{K} 1^{\text {xii }}$ in a monodentate way via $\mathrm{O} 11 A$. The seven-coordinate sphere of K 3 is built up from three $Y^{4-}$ anions and two water molecules (Fig. $5 c$ and Table 5). The ( $\mathrm{III} a$ ) anion is bonded to $\mathrm{K} 3^{\mathrm{xvi}}$ through a bidentate acetate group and coordinates to $\mathrm{K} 3^{\mathrm{xv}}$ in a monodentate manner via $\mathrm{O} 41 A$. The (IIIb) anion coordinates to K3 in a bidentate manner through $\mathrm{O} 22 B$ and $\mathrm{O} 42 B$ atoms of acetate groups bonded to two different N atoms which results in the formation of an 11-membered ring, as in (II) and in $\mathrm{Rb}_{2}\left[\mathrm{H}_{2} \mathrm{ed}\right.$ ta] $2 \mathrm{H}_{2} \mathrm{O}$ (Cotrait, 1970). Such an 11-membered ring can be distinguished at K 5 as well (Table 5). The environment of K 4 is made up of three $Y^{4-}$ ions and two water molecules (Table 5). The coordination spheres of the K6-K8 cations are built by anions linked to $\mathrm{K}^{+}$ions through monodentate carboxylate groups and water molecules.

The shortest K…K distances are in the range 3.6949 (9)4.4803 (15) $\AA$, where adjacent $\mathrm{K}^{+}$cations are bridged by edta anions via O atoms, giving a three-dimensional polymeric structure. Compound (III) also contains numerous $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds in which the O atoms of anions and water molecules are involved (Table 3). Adjacent anions and water molecules form layers, while $\mathrm{K}^{+}$cations act as linkers between such layers. The $Y^{4-}$ anions, $\mathrm{K}^{+}$cations and water molecules are arranged in ribbons extending along the [001] direction (Fig. 3b). Weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds are also observed between neighbouring anions, and between anions and water molecules.

The dipotassium edta salt, (I), was initially studied by Cotrait (1969) who used photographic methods at room temperature. This salt contains an $\mathrm{H}_{2} Y^{2-}$ anion, two $\mathrm{K}^{+}$ cations and two water molecules. In the $\mathrm{H}_{2} Y^{2-}$ anion, the $\mathrm{NH}^{+} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}^{+}$fragment adopts a gauche conformation. Atoms N 1 and N 2 are both involved in intramolecular bi- and trifurcated hydrogen bonds, respectively (Table 1 and Fig. 1a). This anion is also found in $\mathrm{Rb}_{2}\left[\mathrm{H}_{2}\right.$ edta $] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Cotrait, 1970) and $\mathrm{Na}_{2}\left[\mathrm{H}_{2}\right.$ edta $] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Font-Bardia et al., 1993). The $\mathrm{H}_{2} Y^{2-}$ ion in (I) has a different overall conformation in relation to the relevant anions in the dirubidium and disodium edta salts (Cotrait, 1970; Font-Bardia et al., 1993), in which $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{~N}$ units adopt an antiperiplanar conformation and the acetate arms have a different geometry. However, the anion in (I) has similar overall geometry to the $Y^{4-}$ ligand in complexes such as $\mathrm{Li}[\mathrm{Fe} Y] \cdot 3 \mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{4}[\mathrm{CoY}] \cdot 2 \mathrm{H}_{2} \mathrm{O},\left[\mathrm{Mg} Y\left(\mathrm{H}_{2} \mathrm{O}\right)\right][\mathrm{Mg}$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O},\left[\mathrm{Ca}_{2} Y\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ (Lind et al., 1964; Weakliem \& Hoard, 1959; Pozhidaev et al., 1973; Barnett \& Uchtman, 1979). Such similarity may result from the occurrence of intramolecular hydrogen bonds of the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ type in (I) mentioned above.

In the coordination polyhedron of K 1 in (I), the edta anion acts as a tridentate ligand (Fig. 6). The coordination sphere of K1 involves four different edta anions and one water molecule, $\mathrm{O} 1 W$. The coordination is via two O atoms (O11 and O21) derived from two different acetate groups joined to the N 1 atom and via O32. The symmetry-related anions which occupy positions in the coordination sphere of the K1 cation are bonded to K 1 in a monodentate fashion via atoms O12 ${ }^{\mathrm{i}}, \mathrm{O} 22^{\mathrm{ii}}$ and O31 ${ }^{\text {iii }}$ (Table 5 and Fig. 6). Similarly, the coordination sphere of the K 2 cation involves four $\mathrm{H}_{2} Y^{2-}$ anions and one water molecule ( $\mathrm{O} 2 W$ ). However, two anions chelate K 2 through bidentate carboxylate groups (O21/O22 and $\mathrm{O} 41^{\mathrm{v}} / \mathrm{O} 42^{\mathrm{v}}$ ), while the other two are

Figure 7
The molecular structures for the $\mathrm{H}_{2} Y^{2-}$ anion in (I) and the $\mathrm{H} Y^{3-}$ anion in (II) (top). A comparison of the geometry of respective anions (bottom). The common reference points are $\mathrm{N} 1, \mathrm{C} 1, \mathrm{C} 2$ and N 2 .
bonded in a monodentate manner through $\mathrm{O} 11^{\mathrm{ii}}$ and $\mathrm{O} 31^{\mathrm{iv}}$ (Table 5).

As with compounds (II) and (III), compound (I) has a three-dimensional polymeric structure in which potassium cations are bridged by acetate O atoms. Additionally, $\mathrm{K} \cdots \mathrm{O}$ interactions result in tetrameric centrosymmetric motifs where the shortest K. $\cdot \mathrm{K}$ distances are in the range 3.6987 (10)4.6515 (11) A (Fig. 6 and Table 5).

The crystal structure of (I) features a three-dimensional network of intermolecular hydrogen bonds of the $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ types (Table 1). As in (II) and (III), a layered architecture built of anions, water molecules and $\mathrm{K}^{+}$cations is observed.

Consideration of the geometries of the anions in (I)-(III) leads to the following conclusions. The preferred conformation of the $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{~N}$ unit of anions in (I)-(III) is synclinal. The overall geometry of the edta anions in potassium salts can be classified into two basic types. The first is formed by anions in (II) and (III), the overall conformations of which are very similar, with small differences in the spatial arrangement of the corresponding acetate groups (Fig. 7), whereas a distinctly different conformation is adopted by the anion in (I) (Fig. 7). The overall conformation of $\mathrm{H}_{2} Y^{2-}$ in (I) is similar to that in the complexes noted above, in which the acetate arms of $Y^{4-}$ are involved in five-membered rings with a metal atom. The values of $\mathrm{C}-\mathrm{N}_{\text {protonated }}$ bond lengths in (I) are similar to values in (II), and the relevant values of C$\mathrm{N}_{\text {unprotonated }}$ bond lengths in (II) and (III) are also similar (Table 4).

## Experimental

The three title salts were obtained by reactions of edta with potassium hydroxide and they were crystallized from aqueous solutions under a gentle stream of nitrogen. All operations were performed at room temperature. All compounds used for syntheses were obtained commercially and not further purified. Contrary to our procedures of preparation, both the corresponding disodium and tetrasodium edta salts were obtained in the reactions between edta and disodium carbonate in aqueous solutions at controlled pH (Font-Bardia et al., 1993).

For the synthesis of (I), edta ( $0.16 \mathrm{~g}, 0.55 \mathrm{mmol})$ and potassium hydroxide ( $0.064 \mathrm{~g}, 1.1 \mathrm{mmol}$ ) were mixed in a $1: 2$ molar ratio. A small amount of distilled water (about 5 ml ) was added, and the mixture was stirred for about 15 min . The solution ( pH value ca $4-$ 4.5) was filtered to remove insoluble crystals of edta and crystals were grown by evaporation. Crystals have the same unit-cell dimensions as those reported by Cotrait (1969).

Compound (I) was also obtained as a result of mixing edta with potassium hydroxide in a 1:3 molar ratio. $\mathrm{KOH}(2.318 \mathrm{~g}, 41.39 \mathrm{mmol})$ was dissolved in distilled water (about 7 ml ) and edta ( 4.031 g , 13.79 mmol ) added to this solution. This mixture was stirred at room temperature until a clear solution was obtained. Crystallization was carried out by evaporation as in the case of the previous procedure. Crystals in the form of long plates were obtained from a solution with a pH of about 6.5-7.

For the synthesis of (II), potassium hydroxide $(0.3832 \mathrm{~g}$, 6.843 mmol ) was dissolved in a minimal amount of distilled water. Edta ( $0.5003 \mathrm{~g}, 1.712 \mathrm{mmol}$ ) was added to give a molar ratio of 4:1. Continuous stirring gave a clear solution with a pH of about 10.5 . Evaporation from the solution over the course of 1 d gave colourless crystals in the form of plates.

The crystalline salt (III) was obtained as a result of the reaction of edta with potassium hydroxide mixed in a 1:5 molar ratio. Preparative procedures were performed as in the case of salt (II). KOH ( 1.85 g , 33.4 mmol ) was dissolved in a minimal amount of distilled water. Edta ( $1.928 \mathrm{~g}, 6.597 \mathrm{mmol}$ ) was added (the pH was about 13). Evaporation from the solution under a nitrogen stream yielded block-like crystals.

difference Fourier maps but were introduced in positions calculated from geometry, with $\mathrm{N}-\mathrm{H}=0.93 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{N})$. The methylene H atoms in (I)-(III) were treated as riding atoms in geometrically idealized positions, with $\mathrm{C}-\mathrm{H}=0.99 \AA$ and $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\text {eq }}(\mathrm{C})$.

In (III), partial disorder is present in the case of one acetate group (O31B, O32B and C31B), certain water molecules (O7W, O8W and O9W) and the K7 cation. Disorder of the carboxylate O atoms was identified from the difference Fourier map peaks close to O31B and O32B at distances of approximately 0.52 and $0.42 \AA$, respectively. Because both O atoms and C31B belong to the same carboxylate group, the disorder was modelled for each of them over two positions, with occupancies of 0.793 (11) and 0.207 (11); the minor-occupancy components were refined isotropically.

Additionally, two peaks in the difference Fourier map were interpreted as disorder of the O atoms of water. These peaks were at distances of 0.61 and $0.74 \AA$ from O7W and O9W, respectively, and were introduced as 071 W and O 91 W . O7W was modelled as disordered over two positions with occupancies of 0.892 (10) and

Table 5
Coordination spheres of potassium cations in salts (I)-(III), with $\mathrm{K}-\mathrm{O}$, $\mathrm{K}-\mathrm{N}$ and the shortest $\mathrm{K} \cdots \mathrm{K}$ distances $(\AA)$ given.

0.108 (10). The sum of the occupancies of O 9 W and O 91 W was smaller than unity. Therefore the disorder was modelled with occupancies of 0.282 (14) and 0.298 (14) for $\mathrm{O} 9 W$ and $\mathrm{O} 91 W$, respectively. The K7 cation was also disordered over two positions, with occupancies of 0.947 (8) and $0.053(8)$. O8W was located in a difference Fourier map and refined with an occupancy of 0.267 (2).

The H atoms of water molecules $\mathrm{O} 7 W$, O 8 W and $\mathrm{O} 9 W$ were located in a difference Fourier map and introduced with distance restraints for the $\mathrm{O}-\mathrm{H}$ and $\mathrm{H} \cdots \mathrm{H}$ distances of 0.84 (2) and 1.41 (2) $\AA$, respectively. In the last stages of refinement, these $H$ atoms were permitted to ride at the positions previously established, with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$, giving $\mathrm{O}-\mathrm{H}$ distances in the range $0.83-$ 0.87 Å.

For all three salts, data collection: CrysAlis CCD (Oxford Diffraction, 2008); cell refinement: CrysAlis RED (Oxford Diffraction, 2008); data reduction: CrysAlis RED; program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL97 (Sheldrick, 2008); molecular graphics: XP in SHELXTL (Sheldrick, 2008); software used to prepare material for publication: SHELXL97 and publCIF (Westrip, 2010).
