In the title compound, $[\text{Cr}(\text{C}_{24}\text{H}_{20}\text{P}_2\text{S})(\text{CO})_5]$, the key bond lengths are P_1-P_2 2.2659 (15), P_2-S 1.9531 (15), P_1-C 1.830, 1.833 (3), P_2-C 1.821, 1.822 (3) and P_1-Cr 2.3921 (13) Å. The conformation about the P–P bond is defined by the torsion angle S–P2–P1–Cr of $-58.60(7)^\circ$.

Comment

The title compound, (I), arose during studies (see *Experimental*) of thioureas substituted with phosphorus-containing groups (Farkens, 1991). It was characterized by this structure determination.

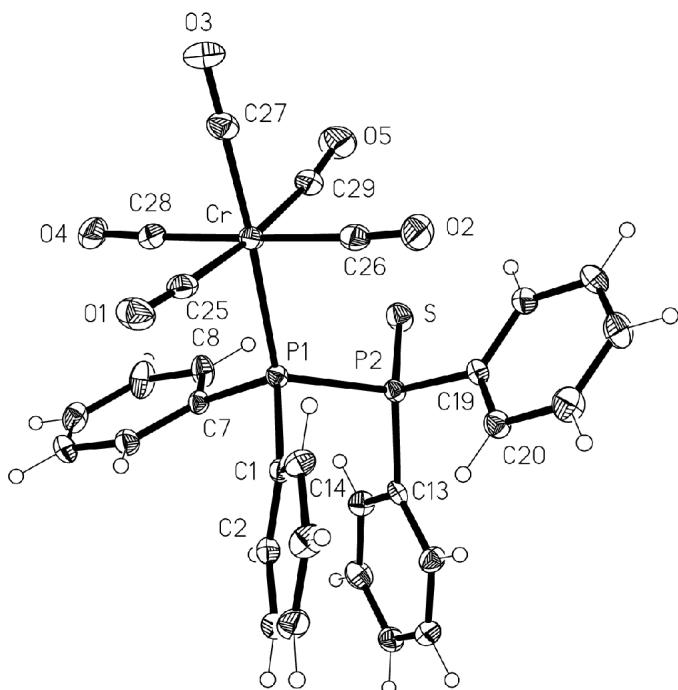

The molecular structure of (I) is shown in Fig. 1. A search of the Cambridge Structural Database (CSD, Version of April 2002; Allen & Kennard, 1993) revealed no other complexes of any tetra(organyl)diphosphine monosulfide (in the strict sense of a compound containing a P–P bond). The key bond lengths are P_1-P_2 2.2659 (15), P_2-S 1.9531 (15), P_1-C 1.830, 1.833 (3) and P_2-C 1.821–1.822 (3) Å. These may be compared, although the two systems clearly differ chemically in many respects, with values for uncomplexed tetramethyl-diphosphane monosulfide (Gruber *et al.*, 1990): P–P 2.201 (1), P–S 1.970 (1), $\text{P}^{\text{III}}-\text{C}$ 1.830 and 1.834 (1), and $\text{P}(\text{S})-\text{C}$ 1.803 and 1.803 (1) Å. The P–P bond in (I) may be regarded as long, and it is reasonable to propose steric effects as the cause. A CSD search revealed 57 structures with $(\text{C})_2\text{P}-\text{P}(\text{C})_2$ single bonds, involving 69 bonds in the range 2.104–2.310 Å (average 2.216 Å).

The P–Cr distance is 2.3921 (13) Å, and the Cr–C bond *trans* to Cr–P is by far the shortest, at 1.865 (4) Å, *cf.* average 1.903 Å for the other four Cr–C bonds. The conformation about the P–P bond is defined by the torsion angle S–P2–P1–Cr of $-58.60(7)^\circ$ (in the above-mentioned diphosphine monosulfide, the S atom is *trans* to the lone pair at the other phosphorus). As expected, the largest angles at phosphorus are those involving the Cr atom at P1 and the S atom at P2.

Two short H···O contacts could reasonably be interpreted as weak hydrogen bonds (Table 2).

Experimental

The reaction between (norbornadiene) $\text{Cr}(\text{CO})_4$ and *N,N'*-bis(diphenylphosphino)-*N,N'*-dimethylthiourea in dichloromethane led to

**Figure 1**

The molecule of compound (I) in the crystal. Displacement ellipsoids represent 30% probability levels. H-atom radii are arbitrary.

a complex mixture of products. The mixture was dissolved in diethyl ether, from which the title compound crystallized in 13% yield (Farkens, 1991). The decomposition of the thiourea to tetraphenyl-diphosphine monosulfide has been observed before in our laboratory (Gruber, 1989).
