## Key indicators

Single-crystal X-ray study

$T = 293\text{ K}$

Mean  $\sigma(\text{Mn}-\text{O}) = 0.009\text{ \AA}$

Disorder in main residue

$R$  factor = 0.052

$wR$  factor = 0.156

Data-to-parameter ratio = 11.0

For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.

 $\text{Ag}_{1.49}\text{Mn}_{1.49}^{\text{II}}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$ 

The compound  $\text{Ag}_{1.49}\text{Mn}_{1.49}^{\text{II}}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$  (silver manganese arsenate) was prepared by a solid-state reaction. It crystallizes in the monoclinic system in space group  $C2/c$ . The three-dimensional network is built up from  $\text{MnO}_6$  octahedra, sharing edges which are linked together by the arsenate groups ( $\text{AsO}_4$ ). This arrangement delimits two types of hexagonal tunnels which accommodate  $\text{Ag}^+$  cations. The compound is isostructural with the compounds  $X(1)X(2)M(1)M(2)_2(\text{PO}_4)_3$  of the alluaudite structure.

## Comment

$\text{Ag}_{1.49}\text{Mn}_{1.49}^{\text{II}}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$  crystallizes in the monoclinic space group  $C2/c$  and is isostructural with the compounds  $X(1)X(2)M(1)M(2)_2(\text{PO}_4)_3$  (Moore, 1971; Yakubovitch *et al.*, 1977) of the alluaudite structure type. The framework of  $\text{Ag}_{1.49}\text{Mn}_{1.49}^{\text{II}}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$  consists of infinite chains of  $\text{MnO}_6$  octahedra, sharing two skew edges, running parallel to the  $[010]$  direction and having an  $\text{Mn1}-\text{Mn2}-\text{Mn2}$  sequence. A projection of the structure, showing the displacement ellipsoids, is presented in Fig. 1.

In each chain, repetition of the  $\text{Mn1O}_6$  and  $\text{Mn2O}_6$  octahedra is ensured by  $c$ -glides and inversion centers, respectively. Atoms  $\text{As2}$ ,  $\text{Mn1}$  and  $\text{Ag1}$  have twofold symmetry,  $\text{Ag2}$  are on inversion centers and all other atoms are in general positions. The infinite chains are linked by  $\text{As1O}_4$  and  $\text{As2O}_4$  tetrahedra to form sheets parallel to  $(010)$ . The  $\text{As2O}_4$  tetrahedra share all four of their vertices with the  $\text{MnO}_6$  octahedra, two with one chain and two with an adjacent chain. The  $\text{As1O}_4$  tetrahedron shares its four oxygen vertices with four different  $\text{MnO}_6$  octahedra belonging to three chains, two from the same

Figure 1

A projection of the structure, showing displacement ellipsoids at the 50% probability level.

**Figure 2**  
View showing the association between  $\text{AsO}_4$  tetrahedra (purple) and  $\text{MnO}_6$  octahedra (cyan).

**Figure 3**  
Projection of the structure of  $\text{Ag}_{1.49}\text{Mn}_{1.49}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$  along the [001] direction. In this presentation, the corners of the octahedra and tetrahedra are O atoms and the Mn and As atoms are at the center of each octahedron and tetrahedron, respectively. Small solid circles are Ag atoms.

chain and two from two different chains (Fig. 2). The  $\text{MnO}_6$  octahedra appear to be highly distorted, especially around Mn1, for which the angle subtended by two of the *trans* O atoms is  $143.9(2)^\circ$ . This distortion probably occurs as a result

of the need to accommodate the connectivity of the  $\text{AsO}_4$  tetrahedra, which are rather rigid entities and are responsible for holding adjacent chains together. This framework defines large tunnels running along the *c* direction. one tunnel along  $(0,0,z)$  and the other along  $(0,0.5,z)$  (Fig. 3). The silver cations  $\text{Ag}1^+$  and  $\text{Ag}2^+$  partially occupy sites in these tunnels. They exhibit two modes of coordination:  $\text{Ag}1^+$  [site-occupation factor = 0.870 (7)], located in the second type of tunnel, has a square-planar environment, similar to the situation observed in  $\text{AgCo}_3\text{PO}_4(\text{HPO}_4)_2$  (Guesmi & Driss, 2002) and  $\text{Ag}2^+$  [site-occupation factor = 0.620 (7)], located in the first type, is linked to six O atoms. For electroneutrality, it is supposed that Mn2 has the average oxidation state 2.69, as indicated by the bond-valence sum (Brown & Altermatt, 1985) and based on parameters for  $\text{Mn}^{2+}-\text{O}$ ; then the total charge contributed by Mn1 and Mn2 is  $1 \times 2 + 2 \times 2.69 = 7.38$ , which leaves a charge of 1.62 to be provided by the two tunnel sites, quite close to the value of 1.49 provided by the X-ray refinement.

## Experimental

Single crystals of  $\text{Ag}_{1.49}\text{Mn}_{1.49}\text{Mn}_{1.51}^{\text{III}}(\text{AsO}_4)_3$  were prepared by a conventional solid-state reaction.  $\text{NH}_4\text{H}_2\text{AsO}_4$ , MnO and  $\text{AgNO}_3$  in a 1:2:3 ratio were ground together under acetone in an agate mortar. The mixture was heated in a porcelain crucible at 673 K for 4 h, cooled to room temperature, reground, and heated at 1073 K for 24 h, then cooled slowly to room temperature at a rate of  $5 \text{ K h}^{-1}$ . The product was washed with hot water. Brown parallelepiped-shaped crystals of the title compound were extracted. Their qualitative analysis by an electron microscope probe revealed them to contain Ag, As and Mn atoms.

### Crystal data

$\text{Ag}_{1.49}\text{Mn}_3(\text{AsO}_4)_3$   
 $M_r = 742.29$   
 Monoclinic,  $C2/c$   
 $a = 12.262(2) \text{ \AA}$   
 $b = 12.934(3) \text{ \AA}$   
 $c = 6.7070(9) \text{ \AA}$   
 $\beta = 113.690(2)^\circ$   
 $V = 974.1(3) \text{ \AA}^3$
