Key indicators

Single-crystal X-ray study
T = 293 K
Mean $\sigma(\text{C}-\text{C}) = 0.019 \text{ \AA}$
R factor = 0.038
wR factor = 0.060
Data-to-parameter ratio = 26.8For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.Bis(tetrabutylammonium) decaiodo-tetramercurate(II), $(\text{Bu}_4\text{N})_2[\text{Hg}_4\text{I}_{10}]$ $(\text{Bu}_4\text{N})_2[\text{Hg}_4\text{I}_{10}]$ is the first compound for which tetranuclear anions $[\text{Hg}_4\text{I}_{10}]^{2-}$ are observed in its crystal structure. Charge balance is achieved by ordered $[\text{Bu}_4\text{N}]^+$ cations.

Comment

Halogenomercurate(II) anions show a wide variety of steric arrangements, dependent upon the charge and size of the counter-cation(s) and the stoichiometry (Dean *et al.*, 1994; Grdenic *et al.* 1965; House *et al.*, 1994; Serezhkin *et al.*, 2001). Up to now, only one compound has been reported for the $\text{Bu}_4\text{N}/\text{HgI}_2$ system, *viz.* $(\text{Bu}_4\text{N})[\text{HgI}_3]$ contains trigonal planar $[\text{HgI}_3]^-$ units (Goggin *et al.*, 1982).Other discrete iodomercurate(II) anions with different cations that have been reported are the tetrahedral $[\text{HgI}_4]^{2-}$ and the octahedral $[\text{HgI}_6]^{4-}$, as well as the dimeric $[\text{Hg}_2\text{I}_6]^{2-}$ and the trimeric $[\text{Hg}_3\text{I}_8]^{2-}$ units.Recently, we have reported the structure of $(\text{Et}_4\text{N})_2[\text{Hg}_4\text{Cl}_{10}]$ (Nockemann & Meyer, 2002). Bitetrahedral $[\text{Hg}_2\text{Cl}_6]^{2-}$ anions built from two tetrahedra sharing one common edge have two slightly bent HgCl_2 molecules, with $\text{Cl}-\text{Hg}-\text{Cl}$ angles of about 170° , attached to either side so that, altogether, it may be considered as the tetrameric $[\text{Hg}_4\text{Cl}_{10}]^{2-}$ anion. The two terminal mercuric ions exhibit coordination number 2 + 1 in a T-shaped arrangement.The tetrameric anion $[\text{Hg}_4\text{I}_{10}]^{2-}$ in the crystal structure of $(\text{Bu}_4\text{N})_2[\text{Hg}_4\text{I}_{10}]$ may also be derived from bitetrahedral $[\text{Hg}_2\text{I}_6]^{2-}$ units to which two HgI_2 molecules are again attached on either side. The two central tetrahedra are only slightly distorted, with $\text{Hg}-\text{I}$ distances ranging from 2.715 (1) to 2.910 (1) Å. The outer HgI_2 molecules show considerably shorter distances, ranging between 2.617 (1) and 2.647 (1) Å, with $\text{I}-\text{Hg}-\text{I}$ angles of $149.09 (5)$ and $142.93 (4)^\circ$, but the distances to the iodide ions of the edges shared with the central $[\text{Hg}_2\text{I}_6]^{2-}$ are, in turn, much longer, 3.080 (1)–3.316 (1) Å. In summary, in the tetranuclear anion $[\text{Hg}_4\text{I}_{10}]^{2-}$, all mercuric ions may be considered as having coordination number 4, and all tetrahedra share common edges, in contrast to the situation in the tetranuclear $[\text{Hg}_4\text{Cl}_{10}]^{2-}$ where coordination numbers are 4 and 3 (twice each), respectively.In $(\text{Bu}_4\text{N})_2[\text{Hg}_4\text{I}_{10}]$, charge balance is achieved by two crystallographically independent, perfectly ordered tetrahedral $[\text{Bu}_4\text{N}]^+$ cations which are arranged in the crystal

structure, together with the anions, in a 2:1 ratio, as Fig. 1 illustrates.

Experimental

1 mmol (0.369 g) of tetrabutylammonium iodide, $(\text{Bu}_4)\text{NI}$, and 2 mmol (0.454 g) of mercuric iodide HgI_2 , were dissolved by stirring in 50 ml methanol at 323 K until a clear solution was obtained. Yellow single crystals were obtained when the solution was allowed to stand at room temperature for 2 d.
