**Key indicators**

Single-crystal X-ray study

T = 82 K

Mean  $\sigma(\text{C}-\text{C}) = 0.008 \text{ \AA}$ 

R factor = 0.018

wR factor = 0.042

Data-to-parameter ratio = 16.9

For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.

The structure of the title compound,  $[\text{PbBr}_2(\text{C}_3\text{H}_7\text{NO}_2)]$ , contains  $\text{Pb}^{2+}$  ions,  $\text{Br}^-$  ions and  $\beta$ -alanine molecules in their zwitterion form. Each lead(II) ion has a seven-coordinate geometry, with four sites occupied by  $\text{Br}^-$  ions, two by a bidentate carboxylate group and the last by a single O atom. The singly-bridging  $\text{Br}^-$  ions link the  $\text{Pb}^{\text{II}}$  ions into layers that are further aggregated into a three dimensional array by the formation of  $\text{Pb}-\text{O}$  bonds and hydrogen bonds involving the  $-\text{NH}_3^+$  groups.

**Comment**

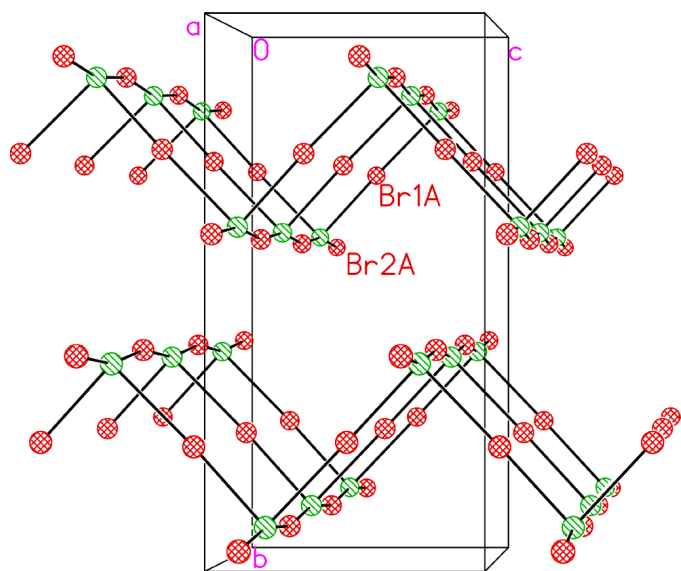

The sevenfold local coordination for the lead(II) ion is shown in Fig. 1, and can conveniently be viewed as a severely distorted octahedron in which one site of the octahedron is occupied by the bidentate carboxylate group. The four  $\text{Pb}-\text{Br}$  bond lengths range from 2.9918 (6) to 3.1731 (5)  $\text{\AA}$ . The carboxylate group in the zwitterion form of the  $\beta$ -alanine molecule coordinates in one octahedral site in a bidentate fashion, while the sixth site is occupied by an O atom from a  $\beta$ -alanine molecule of an adjacent octahedron. The  $\text{Pb}-\text{O}$  distances are 2.533 (3) and 2.600 (4)  $\text{\AA}$  for the O atoms in the bidentate group, and 2.754 (4)  $\text{\AA}$  for the bridging O atom. As anticipated, the angular distortions imposed by the presence of the bidentate group are significant. As is also seen in Fig. 1, the backbone of the  $\beta$ -alanine molecule assumes a *gauche* conformation. As discussed below, this allows the formation of an intramolecular hydrogen bond as well as several other interactions.

Corner-sharing, through the bromide ions on adjacent octahedra, leads to the formation of a two-dimensional structure, as shown in Fig. 2. This layer structure may be viewed as a (110) section of the parent cubic  $AMX_3$  structure. This is a single metal halide layer of the type in the multiple layer  $(\text{NH}_2\text{CINH}_2)_2(\text{CH}_3\text{NH}_3)_{n-1}\text{Sn}_n\text{I}_{3n+1}$  (110) sections reported by Mitzi *et al.* (1995). This is in contrast to the typical (001) section formed by  $(\text{RNH}_3)_2MX_4$  layer perovskite compounds, such as in  $(\beta\text{-alaninium})_2\text{CuX}_4$  salts ( $X = \text{Cl}^-$  and  $\text{Br}^-$ ) (Willett *et al.*, 1981, 1983).

**Figure 1**  
Illustration of the lead(II) ion coordination. Displacement ellipsoids are drawn at the 70% probability level. Suffix letters denote symmetry-generated atoms:  $A$   $x, \frac{1}{2} - y, z - \frac{1}{2}$ ;  $B$   $-x, 1 - y, -z$ ;  $C$   $1 + x, y, z$ .

**Figure 2**  
Illustration of the (110)  $\text{PbBr}_2$  layer.

These metal halide layers are linked together *via* double  $\text{Pb}-\text{O}-\text{Pb}$  bridges (dashed lines, Fig. 3), as well as  $\text{N}-\text{H}\cdots\text{O}$  and  $\text{N}-\text{H}\cdots\text{Br}$  hydrogen bonds (dashed lines, inset, Fig. 3). These  $\text{Pb}-\text{O}$  bonds are 0.15 Å longer than those in the bidentate linkage. The bridging  $\text{Pb}-\text{O}-\text{Pb}$  angle is 109.0 (1)°. The  $-\text{NH}_3^+$  group forms one asymmetric bifurcated hydrogen bond (to two different Br2 atoms, see Table 1) and two normal hydrogen bonds (to Br1 and O1). The intramolecular  $\text{N}-\text{H}\cdots\text{Br}$  hydrogen bond is nearly 0.2 Å longer than the one between layers, presumably because of steric constraints on the conformation of the  $\beta$ -alanine molecule. In addition, there is an electrostatic interaction of the  $-\text{NH}_3^+$  group with an O2 atom from the adjacent layer, in which the  $\text{C}-\text{N}\cdots\text{O}$  angle is close to linear.

**Figure 3**  
Illustration of the interconnection of the  $\text{PbBr}_2$  layers, viewed down the  $a$  direction. The  $b$  axis is horizontal. The bridging  $\text{Pb}-\text{O}$  bonds are shown as dashed lines. The inset shows the hydrogen-bonding contacts.

## Experimental

Crystals of the title compound were prepared by slow evaporation of a solution obtained by dissolving 0.9282 g  $\text{PbBr}_2$  (0.002 mmol) and 0.4550 g  $\beta$ -alanine (0.005 mmol) in 80 ml deionized water that had been acidified with 5 drops of concentrated  $\text{HBr}$ .
