## Key indicators

Single-crystal X-ray study  
 $T = 170\text{ K}$   
Mean  $\sigma(\text{Cl}-\text{O}) = 0.005\text{ \AA}$   
 $R$  factor = 0.020  
 $wR$  factor = 0.043  
Data-to-parameter ratio = 16.0For details of how these key indicators were  
automatically derived from the article, see  
<http://journals.iucr.org/e>.Redetermination of mercury(II) hydroxide  
chlorate(V)

$\text{Hg}(\text{OH})\text{ClO}_3$  is built up from infinite zigzag  $[\text{Hg}(\text{OH})_{2/2}]^+$  chains along [001] and  $[\text{ClO}_3]^-$  ions. These chains are connected *via* weak  $\text{Hg}-\text{O}$  interactions to O atoms of the  $[\text{ClO}_3]^-$  ions, leading to layers parallel to (010).  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds are present between these layers.

## Comment

$\text{Hg}(\text{OH})\text{ClO}_3$  (Weiss *et al.*, 1960), whose structure is re-determined here with considerably greater precision and with the H atom located, is isotypic with  $\text{Hg}(\text{OH})\text{BrO}_3$  (Björnlund, 1971), but different from other basic  $\text{Hg}(\text{OH})X$  compounds, such as  $\text{Hg}(\text{OH})\text{NO}_3$  (Ribar *et al.*, 1971; Matkovic *et al.*, 1974) or  $\text{Hg}(\text{OH})\text{F}$  (Grdenic & Sikirica, 1973; Stalhandske, 1979; Nozik *et al.*, 1979). The structure of  $\text{Hg}(\text{OH})\text{ClO}_3$  contains infinite zigzag  $[\text{Hg}(\text{OH})_{2/2}]^+$  chains along the [001] direction (Fig. 1). The distances [ $\text{Hg}-\text{O} = 2.051(2)\text{ \AA}$ ] and angles [ $(\text{H})\text{O}-\text{Hg}-\text{O}(\text{H}) = 177.9(2)^\circ$  and  $\text{Hg}-(\text{OH})-\text{Hg} = 122.6(2)^\circ$ ] in the chains are comparable with those in  $\text{Hg}_2(\text{OH})[\text{BF}_4]$  (Meyer & Göbbels, 2003) and  $(\text{Hg}_2)\text{Hg}(\text{OH})_2[\text{ClO}_4]_2$  (Wickleder, 2002). These chains are further connected *via* weak  $\text{Hg}-\text{O}$  bonds [ $2.733(3)$  and  $2.763(3)\text{ \AA}$ ] to O atoms of the  $[\text{ClO}_3]^-$  ions, forming layers that are parallel to (010). Taking these weak contacts into account, the coordination number of the mercury ion is '2 + 4'. The stacking direction of the layers is [010]. The layers are connected by  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds (Steiner, 2002), with a  $2.796(6)\text{ \AA}$  ( $\text{O})\text{H}\cdots\text{O}$  distance and a  $164(3)^\circ$   $\text{O}-\text{H}\cdots\text{O}$  angle. The  $[\text{ClO}_3]^-$  ion exhibits the typical pyramidal shape

**Figure 1**

Projection of  $\text{Hg}(\text{OH})\text{ClO}_3$  along the  $a$  axis. The dashed lines show the weak  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds between the layers. Displacement ellipsoids are drawn at the 90% probability level.

due to the lone electron pair on the Cl atom. The distances [1.486 (4) and 1.499 (5) Å] and angles [104.8 (2) and 107.9 (3)°] within the [ClO<sub>3</sub>]<sup>-</sup> ion are similar to those in oxochlorates(V) *M*[ClO<sub>3</sub>]<sub>2</sub>·H<sub>2</sub>O, with *M* = Ba or Pb (Lutz *et al.*, 1985).

The site symmetries are Hg 2, and O1, H, Cl1 and O11 *m*.

## Experimental

Red HgO was dissolved with heating in 10 ml of 10% HClO<sub>3</sub> until a saturated solution was obtained. Colourless rod-shaped crystals were obtained upon cooling and filtration. These crystals were handled under air and an appropriate specimen was sealed in a glass capillary for the X-ray investigation.
