Poly[[dibromomercury(II)]-di- μ -pyrazine- $\kappa^4\text{N:N}'$]

The crystal structure of $[\text{HgBr}_2(\text{Pyp})_2]_n$ (Pyp = pyrazine, $\text{C}_4\text{H}_4\text{N}_2$) consists of almost linear HgBr_2 molecules which are linked by pyrazine molecules to form double strands of a coordination polymer in the [010] direction. The Hg and Br atoms lie on mirror planes.

Comment

The d^{10} closed-shell configuration and relativistic effects (Pyykkö, 1978) cause a pronounced preference of divalent mercury for 'soft' ligands and bonds with high covalent contributions. *N*-Donor ligands have been the focus of particular interest in the literature (*e.g.* Grdenić, 1965; Breiting & Brodersen, 1970). In a systematic study, we have investigated the formation of coordination polymers of mercuric salts with *N*-donor ligands, especially with diazines (Nockemann, 2002; Meyer & Nockemann, 2003).

(I)

The structure of $[\text{HgBr}_2(\text{Pyp})_2]_n$, (I), consists of HgBr_2 units, which lie on mirror planes and are connected to the 1 and 4 positions of four pyrazine molecules, with $\text{Hg}-\text{N}$ distances of 2.719 (4) and 2.844 (4) Å. These slightly bent HgBr_2 molecules [$\text{Hg}-\text{Br} = 2.4691$ (10) and 2.4726 (9) Å; $\text{Br}-\text{Hg}-\text{Br} = 167.78$ (3)°] with a strongly deformed overall octahedral $[\text{HgN}_4\text{Br}_2]$ coordination of mercury are connected to give chains in the [010] direction by quite long $\text{Hg}-\text{N}$ distances [2.844 (4) Å]. Further pyrazine molecules connect these chains to produce double strands, as shown in Fig. 1. Here, the $\text{Hg}-\text{N}$ distance is 2.719 (4) Å. The two $\text{Hg}-\text{N}$ distances are the longest bonds observed in diazine adducts with mercuric bromide. This correlation has also been found for adducts of HgCl_2 , and is a result of the low basicity of pyrazine (Meyer & Nockemann, 2003).

Figure 1
Packing diagram of $[\text{HgBr}_2(\text{Pyp})_2]_n$, viewed approximately down the b axis.

Figure 2
View of a part of the $[\text{HgBr}_2(\text{Pyp})_2]_n$ coordination polymer, showing 50% probability displacement ellipsoids and the atom-numbering scheme.

Experimental

Mercury(II) bromide (0.360 g, 1 mmol) and an excess of pyrazine (3 g, 37.5 mmol) were sealed in a glass ampoule under dry argon. This ampoule was heated to 398 K with a heating rate of 10 K h⁻¹ and kept at that temperature for 7 d, after which it was cooled at a rate of 5 K h⁻¹. $[\text{HgBr}_2(\text{Pyp})_2]_n$ crystallized as brown prisms and could easily be separated from excess pyrazine, which sublimed off to the cooler parts of the ampoule. Attempts to crystallize this compound from aqueous or methanolic solutions led to twinned or poor-quality crystals.
