Key indicators

Single-crystal X-ray study
 $T = 293$ K
Mean $\sigma(\text{C}-\text{C}) = 0.006$ Å
 R factor = 0.041
 wR factor = 0.102
Data-to-parameter ratio = 15.3For details of how these key indicators were
automatically derived from the article, see
<http://journals.iucr.org/e>.A two-dimensional coordination polymer
containing copper(II): poly[[$(1H$ -benz-
imidazole- κN^3)copper(II)]- μ_3 -3-carboxylato-
phenoxyacetato- $\kappa^4\text{O},\text{O}':\text{O}'':\text{O}'''$]

In the title two-dimensional coordination polymer, $[\text{Cu}(\text{C}_9\text{H}_6\text{O}_5)(\text{C}_7\text{H}_6\text{N}_2)]_n$, each Cu^{II} atom exists in a distorted square-pyramidal coordination environment, defined by one N atom from the terminal benzimidazole molecule and four carboxyl O atoms derived from three different 3-carboxylato-phenoxyacetate (3-CPOA) dianions. The tetradentate 3-CPOA ligand forms three bonds to adjacent Cu atoms to form chains that are linked to neighboring chains, *via* a fourth Cu—O bond, so as to form a layer structure that is further stabilized by hydrogen bonds.

Comment

A rational synthetic strategy to manipulate the assembly of bridging ligands and metal centers to generate desired topologies is still one of the great challenges facing chemists working in crystal engineering. These polymeric architectures can be influenced by the degree of deprotonation, the coordination modes and capabilities of the ligands, and the coordination sphere of the metal centers (Kawata *et al.*, 1997; Castillo *et al.*, 2000). In this sense, carboxyphenoxyacetic acids (*i.e.* $n\text{-HO}_2\text{CCH}_2\text{OC}_6\text{H}_4\text{CO}_2\text{H}$ for $n = 2, 3$ and 4) could be regarded as a family of excellent bridging ligands, with both rigid and flexible parts, that could be exploited for the construction of coordination polymers because of their versatile coordination modes and high structural stability. Previously, we have reported the structures of a mononuclear Co^{II} complex (Li *et al.*, 2004) and two one-dimensional Ni^{II} and Mn^{II} polymers (Gu, Gao, Huo *et al.*, 2004; Gu, Gao, Zhao *et al.*, 2004) based on 3- or 4-CPOAH₂ ligands, in which the carboxylate groups act variously as monodentate, tridentate and tetradentate ligands. However, there is limited structural information on high-dimensional polymers derived from these ligands. The hydrothermal reaction technique offers a powerful synthetic route for the preparation of polymeric solids with multi-dimensional structure and thereby complements traditional solution techniques such as evaporation, diffusion and cooling. On the basis of the above, the two-dimensional title complex, $[\text{Cu}(1H\text{-benzimidazole})(3\text{-CPOA})]_n$ (I), has been synthesized, employing hydrothermal methods.

As shown in Fig. 1, the fundamental building unit of complex (I) comprises a five-coordinate Cu^{II} center, one benzimidazole molecule and one 3-CPOA²⁻ ligand. The copper(II) ion is in a square-pyramidal coordination environment. The basal plane is formed by the N1 atom from the benzimidazole molecule and three carboxyl O atoms [O1, O4ⁱⁱ and O5ⁱⁱⁱ] of two different 3-CPOA²⁻ ligands [symmetry code: (ii) $x - \frac{1}{4}, -y + \frac{1}{4}, z + \frac{3}{4}$]. The coordination sphere of the Cu^{II} atom is completed by an apical O atom from another

carboxylate group, and the axial Cu—O1ⁱ [symmetry code: (i) $x, y, z + 1$] bond distance of 2.289 (3) Å is longer, as expected, than those of the basal Cu—O bonds [1.938 (3)–2.040 (3) Å] as a result of the Jahn–Teller effect. The basal plane is not perfectly planar, with an r.m.s. deviation of 0.11 (3) Å, and the Cu atom is displaced by 0.06 (3) Å from the mean basal plane towards the apical site. The dihedral angle between the benzimidazole molecule and aromatic ring of the 3-CPOA²⁻ ligand is 77.2 (3)°. The dihedral angles between the two carboxyl groups and the aromatic ring are 78.5 (4) (O1—C8—O2) and 16.9 (4)° (O4—C16—O4), respectively, and the oxyacetate group is twisted out of the aromatic ring plane, the C10—O3—C9—C8 torsion angle being 85.0 (4)°].

The carboxylate groups in the 3-CPOA²⁻ ligand display two different coordination modes. One acts in a bidentate bridging coordination mode through atoms O1 and O2, whilst the other binds to the Cu^{II} atom in a chelating mode through atoms O4 and O5, forming a four-membered ring. As described, the 3-CPOA²⁻ ligand simultaneously adopts a monodentate mode through atom O1 and a bidentate mode through atoms O4 and O5 to bridge two copper(II) centers, forming a one-dimensional chain structure running along the *a* axis and adopting a corrugated arrangement (Fig. 2). In the polymeric chain, the Cu1[·]··Cu1^{iv} distance is 10.862 (3) Å [symmetry code: (iv) $x + \frac{1}{4}, -y + \frac{1}{4}, z - \frac{3}{4}$]. The benzimidazole molecules reside alternately on opposite sides of the polymeric chain. The

polymeric chains are cross-linked by Cu—O2 bonds to form a two-dimensional open layer with a square grid-like structure parallel to the crystallographic *ac* plane (Fig. 3). The Cu1[·]··Cu1ⁱⁱⁱ and Cu1ⁱⁱⁱ··Cu1^{iv} separations are 4.784 (3) and 7.605 (3) Å, respectively [symmetry code: (iii) $x, y, z - 1$]. The coordinated benzimidazole molecule engages in hydrogen bonding with the adjacent carboxyl O atoms (Table 2 and Fig. 4), contributing to the stabilization of the crystal structure.

Experimental

The title complex was prepared by the addition of a stoichiometric amount of Cu(OAc)₂·H₂O (2.00 g, 10 mmol) and benzimidazole (1.17 g, 10 mmol) to an aqueous solution of 3-CPOAH₂ (1.96 g, 10 mmol); the pH was then adjusted to 7 with 0.1 M NaOH. The mixture was sealed in a 25 ml Teflon-lined stainless steel bomb and held at 423 K for 5 d. The bomb was cooled naturally to room temperature, and blue prismatic crystals were obtained over several days. Analysis calculated for C₁₆H₁₂CuN₂O₅: C 51.13, H 3.22, N 7.45%; found: C 51.30, H 3.27, N 7.41%.
