The families of oxides with stoichiometry RE_2BaMO_5 (where RE is a trivalent rare earth, and M is Co^{2+} , Ni^{2+} , Cu^{2+} , Zn^{2+} , Pd^{2+} or Pt^{2+}) are known as the green phases in studies of Y–Ba–Cu–O superconductor ceramics. These oxides are not superconductors but nevertheless present interesting structural types. In this work, the synthesis and structural characterization using the Rietveld method applied to X-ray powder diffraction data for $Eu_{1.8}La_{0.2}BaZnO_5$ (europium lanthanum barium zinc oxide) are presented. The compound is isostructural with Y_2BaZnO_5 . The two sites for Y^{3+} are occupied by Eu^{3+} , while La^{3+} ions partially occupy one of these sites.

Comment

Eu₂BaZnO₅ belongs to the family of mixed oxides with general stoichiometry RE2BaMO5, in which four different structural types are possible depending on the RE^{3+} and/or M^{2+} ions present in the crystal structure. Each of them is characterized by different coordination polyhedra around the M^{2+} cation (Burdett & Mitchell, 1990; Saez-Puche & Hernandez-Velazco, 1994; Lavat et al., 1992). For type I $(Sm_2BaCuO_5 \text{ type})$, the M^{2+} ions form isolated MO_5 squarepyramidal units in an orthorhombic unit cell, space group *Pnma*, and Z = 4. For type II (Nd₂BaNiO₅ type), the M^{2+} ions form infinite chains of MO₆ octahedra, running parallel to the a axis and also with an orthorhombic unit cell, with space group Immm and Z = 2. In the case of type III (Nd₂BaPtO₅ type), the symmetry is tetragonal, space group P4/mbm, Z = 2. in which M^{2+} ions are in isolated MO_4 square-planar environments. For the last type, type IV (Nd₂BaZnO₅ type), the symmetry is also tetragonal, with space group I4/mcm and Z =4. In that structure, the M^{2+} ions are in isolated MO_4 tetra-

hedra. Due to their structural features and interesting properties, this family of compounds has previously been studied and characterized. However, no report exists to date on the crystallographic characterization of the solid solution of Eu₂BaZnO₅ with La³⁺, which we report here for the case of Eu_{1.8}La_{0.2}BaZnO₅.

The replacement mechanism seems to be given by $Eu^{3+} \longleftrightarrow La^{3+}$. According to this mechanism, the solid solution has the formula $Eu_{2-x}La_xBaZnO_5$ with 0 < x < 0.3. The solubility range is small, taking into account our preliminary X-ray diffraction analysis: the cell parameters for x = 0, 0.2 and 0.3 decrease with x content, following Vegard's law.

The crystal structure of Eu_{1.8}La_{0.2}BaZnO₅ is shown in Fig. 1, which also shows a view of the unit-cell contents. The introduction of the La³⁺ ions generates changes in the unit-cell parameters compared with the data reported by Kaduk *et al.* (1999) for Eu₂BaZnO₅: a = 7.1789 (1) Å, b = 12.53575 (17) Å, c = 5.79103 (8) Å and V = 521.15 ų (Kaduk *et al.*, 1999); parameters from the present work for Eu_{1.8}La_{0.2}BaZnO₅: a = 7.1952 (1) Å, b = 12.5720 (2) Å, c = 5.8035 (1) Å and V = 524.97 (1) ų.

The structure of Eu_{1.8}La_{0.2}BaZnO₅ exhibits three different coordination polyhedra, namely a distorted square-based pyramidal ZnO₅ (Fig. 2a), a type of distorted tricapped quadrangular prismatic BaO₁₁, in which Ba ions are surrounded by 11 O atoms (Fig. 2b), and two non-equivalent distorted monocapped trigonal prisms (Fig. 2c), one of them completely occupied by Eu³⁺ (the EuO₇ polyhedron) and the other with partial substitution of La³⁺ ions (the Eu/LaO₇ polyhedron). This last fact can be supported by the following observations. The average bond distance for EuO₇ polyhedra is 2.35 Å, very close to the sum of the ionic radii reported by Shannon (1976) ($r_{\rm Eu} + r_{\rm O} = 1.01 + 1.38 = 2.39$ Å). In the second monocapped trigonal prism, Eu/LaO₇, the average bond is

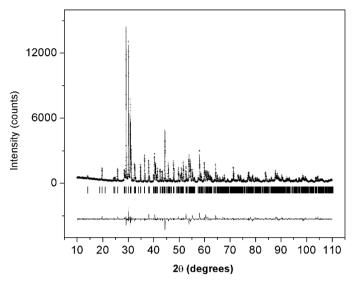

Figure 3 A comparison of observed (cross symbols) and calculated (solid line) intensities for $Eu_{1.8}La_{0.2}BaZnO_5$. The difference pattern appears below. The Bragg peak positions for $Eu_{1.8}La_{0.2}BaZnO_5$ and PtO_2 are represented as vertical marks.

longer (2.38 Å). This distortion is due to the incorporation of the La³⁺ ions on this site. In the same way, the average bond distances found in BaO₁₁ and ZnO₅ polyhedra fit reasonably well with the sum of their ionic radii: mean Ba—O = 3.08 Å, compared with $r_{\rm Ba} + r_{\rm O} = 2.95$ Å, and mean Zn—O = 2.07 Å, compared with $r_{\rm Zn} + r_{\rm O} = 2.06$ Å. These average bond distances are similar to those reported for Eu₂BaZnO₅ by Kaduk *et al.* (1999).

Experimental

The title compound was synthesized by a solid-state reaction. Stoichiometric quantities of 0.6093, 0.4595, 2.7834 and 1.1478 g for the starting reactants Eu₂O₃ (99.99%, Aldrich), La₂O₃ (99.99%, Aldrich), BaCO₃ (99.99%, Aldrich) and ZnO (99.99%, Aldrich), respectively, with a total weight of 5 g, were mixed with acetone for at least 10 min and then powdered in an agate mortar. The powder was heated for a few hours in air at 973 K using a platinum crucible in order to expel CO₂. Finally, the compound was fired at 1473 K for 2–3 d. Because Eu_{1.8}La_{0.2}BaZnO₅ can be easily hydrated, it was kept in a desiccator.

The starting set of parameters to perform a Rietveld refinenment for Eu_{1.8}La_{0.2}BaZnO₅ was taken from the data reported by Kaduk et al. (1999) for the isostructural compound Eu₂BaZnO₅. The structure was refined against the powder diffraction data by the Rietveld method, using a pseudo-Voigt function modified by Thompson et al. (1987) to generate the line shape of the diffraction peaks. The background was initially refined by means of a linear interpolation between 70 background points with refinable heights. At the end of the refinement, the values for all of these background heights were fixed. The refinement was performed by describing the symmetry in the space group *Pbnm* (No. 62), which is a non-standard setting (cab axis reordering) for the standard symbol *Pnma*. We used this setting in order to facilitate a comparison with other previously reported isostructural compounds, in which the Pbnm setting was also used, e.g. Y₂BaZnO₅ (Michel & Raveau, 1983), Dy₂BaZnO₅ (Mueller-Buschbaum & Rabbow, 1993), Ho₂BaZnO₅ and Er₂BaZnO₅ (Wong-Ng et al., 1998), and Eu₂BaZnO₅, Sm₂BaZnO₅, Gd₂BaZnO₅ and Tm₂BaZnO₅ (Kaduk et al., 1999). The following parameters were refined: zero point, scale factor, unit-cell dimensions, half-width, pseudo-Voigt parameters for the peak shape, and positional and isotropic displacement parameters. For the occupation factors, we started the refinement considering the amount of La³⁺, equally distributed over the two Eu³⁺ sites in Eu₂BaZnO₅ (i.e. 0.9 and 0.1 for Eu³⁺ and La³⁺, respectively, in each of the two sites). Keeping the

occupation factors fixed, we found unreasonable isotropic displacement parameters, i.e. very high on one site and very low (almost negative) on the other. Because atomic sites corresponding to smaller or negative values of displacement parameters can be interpreted as sites in which elements of higher atomic numbers should be located, we tried to improve our results by placing all the La³⁺ cations in the site with the higher displacement parameter (with occupation factors of 0.8 for Eu³⁺ and 0.2 for La³⁺), keeping the other site with Eu³⁺ cations only (occupation factor of 1.0). In this way, we found reasonable displacement parameters. Refinement of the occupation factors was not included in the final refinement because it did not allow the attainment of stable behaviour, so convergence was not reached. The fixed occupation factors for the Eu³⁺ and La³⁺ cations cited above were assigned according to the data estimated from the composition of the reactants used. These findings are in agreement with the longer bonds found on the site with incorporated La³⁺ cations, as mentioned in the Comment section. A small quantity of PtO₂ was refined as a secondary phase, a product of a chemical reaction with the crucible employed. The data for the refinement of this secondary phase were obtained from the data reported for β -PtO₂ by Siegel et al. (1969). According to the refinement, the weight fractions for Eu_{1.8}La_{0.2}BaZnO₅ and PtO₂ were 99.5 (1) and 0.5 (1)%, respectively. The results of the Rietveld refinement are shown in Fig. 3.

Data collection: *DIFFRAC/AT* (Siemens, 1993); cell refinement: *DICVOL91* (Boultif & Louer, 1991); program(s) used to refine structure: *FULLPROF* (Rodríguez-Carvajal, 1990); molecular graphics: *ATOMS* (Dowty, 2000); software used to prepare material for publication: *ATOMS*.
