Key indicators

Single-crystal X-ray study
 $T = 293\text{ K}$
 Mean $\sigma(\text{C}-\text{C}) = 0.009\text{ \AA}$
 R factor = 0.049
 wR factor = 0.127
 Data-to-parameter ratio = 13.7

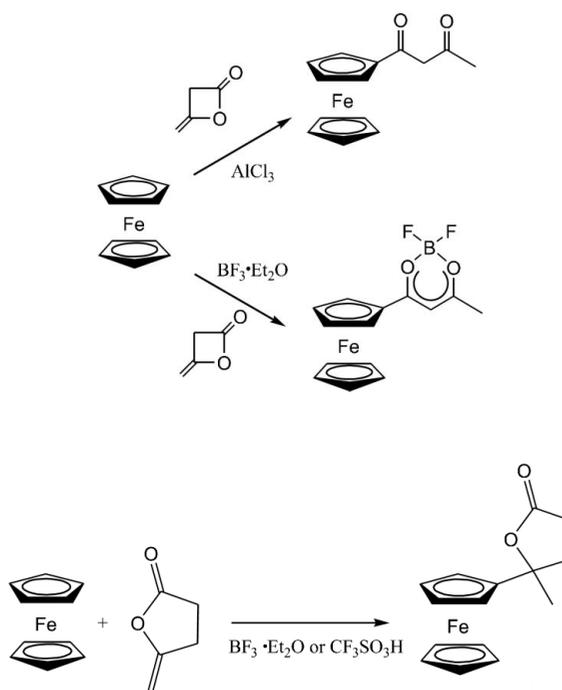

For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.

In the molecular structure of 5-ferrocenyl-5-methyltetrahydrofuran-2-one, $[\text{Fe}(\text{C}_5\text{H}_5)(\text{C}_{10}\text{H}_{11}\text{O}_2)]$, the five-membered heterocyclic ring adopts a distorted envelope conformation. The ferrocenyl substituent is in an equatorial position with respect to this ring. In the crystal structure, there are close $\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\pi$ intermolecular contacts.

Comment

We have reported on the Friedel–Crafts reaction of ferrocene with diketene (Plażuk *et al.*, 2001). This reaction proceeds with an opening of the four-membered ring of diketene and leads to acetoacetylferrocene or the BF_2 -chelated compound. We perceived that this outcome might be due to the strain present in diketene and that, therefore, it would be of interest to study the reactivity of ferrocene toward the essentially unstrained ω -methylene lactones, such as γ -methylene- γ -butyrolactone. We found that ferrocene reacts with this lactone in dichloromethane at room temperature in the presence of BF_3 and Et_2O (molar ratio ferrocene:lactone:acid 1:2:4) to afford the addition product of the metallocene to the exocyclic olefinic bond, namely 5-ferrocenyl-5-methyldihydrofuran-2-one, (I), in 23% isolated yield. A better yield of (I) (73%) was obtained when BF_3 and Et_2O were replaced by $\text{CF}_3\text{SO}_3\text{H}$.

The title compound has been reported previously, prepared in 50% yield by the reaction of ferrocene with the isomeric

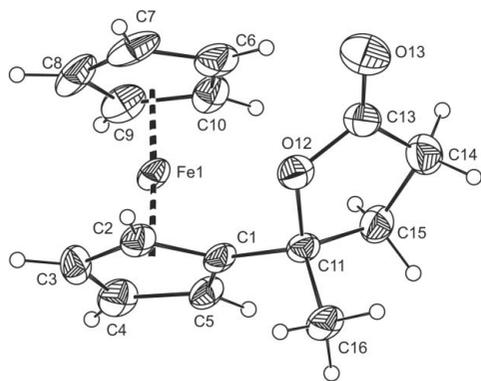

Figure 1

A view of the molecule of (I), showing the atomic numbering scheme. Displacement ellipsoids are drawn at the 40% probability level and H atoms are shown as small spheres of arbitrary radii.

γ -methylene- γ -butyrolactone, angelica lactone, in the presence of AlCl_3 (Sališova *et al.*, 1987). However, its crystal structure has not been reported until now.

Fig. 1 shows a displacement ellipsoid plot of (I), with the atom-labelling scheme. The molecule of (I) consists of the ferrocenyl moiety substituted with a five-membered heterocyclic lactone ring. The ferrocene adopts an eclipsed conformation, with an average C–Cg1–Cg2–C torsion angle of $4.2(4)^\circ$ (Cg1 and Cg2 are the centroids of the C1–C5 and C6–C10 rings, respectively). The overall geometry of this molecular fragment shows no unexpected features. The cyclopentadienyl rings are essentially planar within experimental error and the C–Fe distances range from 2.029(6) to 2.054(6) Å.

The heterocyclic ring of (I) is not planar, as three C atoms (C11, C14 and C15) are sp^3 hybridized. The total puckering amplitude calculated for the five atoms of this ring is $q_2 = 0.210(5)$ Å and the maximum deviation from the least-squares plane is 0.179(1) Å for atom C14. Analysis of the puckering parameters [$\varphi_2 = -0.39(2)^\circ$] (Cremer & Pople, 1975), as well as the asymmetry parameters [$\Delta_s = 0.09(3)$] (Nardelli, 1996), indicates that the lactone ring adopts a distorted envelope conformation, with a pseudo-mirror passing through atom C15 and the midpoint of the O12–C13 bond.

The unexpected molecular feature of (I) is the equatorial position of the ferrocenyl group with respect to the heterocyclic ring. Atom C16 deviates from the lactone mean plane by 1.533(3) Å, while atom C1 is situated much closer but on the opposite side, at a distance of 0.905(4) Å from the plane. The molecular conformation can be confirmed by the C1–C11–O12–C13 and C16–C11–O12–C13 torsion angles (Table 1). In addition, the dihedral angle between the least-squares planes of the lactone and the substituted cyclopentadienyl rings is $41.07(3)^\circ$. To determine the reason for this molecular arrangement we examined closely the intermolecular interactions which may stabilize the conformation observed in the crystalline state.

Weak C–H \cdots O hydrogen bonds link molecules related by 2_1 screw axes into extended chains parallel to the [010] direction (Table 2). This topological motif corresponds to the

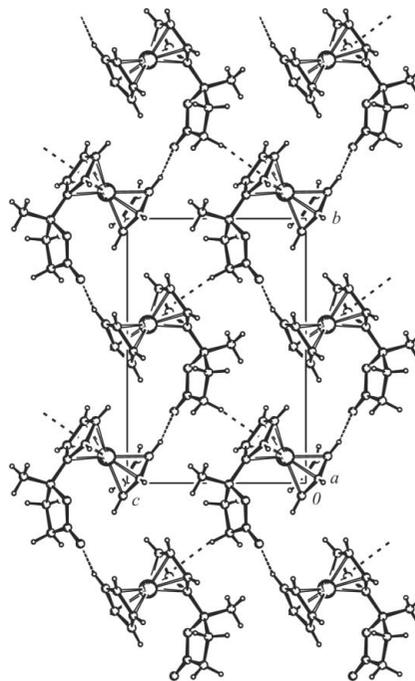

Figure 2

The crystal packing of (I), viewed along the *a* axis, with the intermolecular contacts indicated by dashed lines.

first level graph-set descriptor $C(9)$ (Etter *et al.*, 1990). In addition, the axially substituted H14 atom acts as a donor in a C–H $\cdots\pi$ interaction (Table 2) to link chains into sheets parallel to the *bc* plane. The resulting pattern of intermolecular interactions is shown in Fig. 2.

Interestingly, compound (I) crystallizes in the non-centrosymmetric $P2_1$ group, despite the non-stereospecific synthesis, in which both configurations should be obtained. It is probable that the sample underwent spontaneous resolution upon crystallization. In the crystal structure of (I), the chiral centre at C11 has the *R* configuration. It can be argued that the space-group symmetry is required to give intermolecular interactions and efficient crystal packing of molecules.

Experimental

To a solution of ferrocene (187 mg, 1 mmol) in dichloromethane (10 ml) was added trifluoromethanesulfonic acid (600 mg, 4 mmol) and then, dropwise, a solution of γ -methylene- γ -butyrolactone (196 mg, 2 mmol) in dichloromethane (5 ml). The reaction mixture was stirred for 5 h at room temperature and poured into water. The organic layer was separated and the aqueous layer extracted three times with dichloromethane. After flash chromatography (silica gel/chloroform), the organic extracts afforded the product, (I) (yield 206 mg, 73%). Spectroscopic analysis: ^1H NMR (200 MHz, CDCl_3 , δ , p.p.m.): 1.74 (*s*, 3H), 2.22–2.49 (*m*, 2H), 2.66–2.74 (*m*, 2H), 4.13 (*bs*, 3H), 4.20 (*bs*, 6H); ^{13}C NMR (50 MHz, CDCl_3 , δ , p.p.m.): 28.06, 29.65, 35.95, 65.33, 66.08, 68.37, 68.50, 69.06, 85.41, 93.22, 176.71; IR (KBr, ν , cm^{-1}): 1761. Analysis calculated for $\text{C}_{15}\text{H}_{16}\text{FeO}_2$: C 63.41, H 5.68%; found: C 62.98, H 5.74%. Orange crystals of compound (I) suitable for X-ray diffraction were obtained after recrystallization from layered dichloromethane–hexane by slow evaporation of the solvents at room temperature.
