## Key indicators

Single-crystal X-ray study  
 $T = 298$  K  
 Mean  $\sigma(\text{C}-\text{C}) = 0.004$  Å  
 $R$  factor = 0.042  
 $wR$  factor = 0.120  
 Data-to-parameter ratio = 13.0

For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.

In the crystal structure of the title compound,  $\{[\text{Zn}(\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_6)(\text{H}_2\text{O})_3] \cdot 2\text{H}_2\text{O}\}_n$ , the  $\text{Zn}^{\text{II}}$  atom is located on a twofold axis and is coordinated by two carboxylate O atoms and three water O atoms in a trigonal-bipyramidal geometry. The diacetate ligands connect  $\text{Zn}^{\text{II}}$  atoms to generate one-dimensional zigzag chains, which are linked together by intermolecular hydrogen bonding to form a three-dimensional supramolecular framework.

## Comment

Considerable effort has been devoted to the design and synthesis of self-assembled coordination polymers owing to their potential applications as functional materials (Janiak, 2003; James, 2003). An emerging approach in the rational assembly of coordination polymers is through the organic ligand as a spacer for linking metal atoms (O'Keeffe *et al.*, 2000). Accordingly, the structures of coordination polymers can be ascribed to the coordination interactions between organic ligands and metal atoms, as well as other non-covalent interactions such as hydrogen bonding and  $\pi$ - $\pi$  stacking (Moulton & Zaworotko, 2001). Moreover, the conformations of organic ligands also have important influences on the structures. To avoid the structural complication arising from the conformations of the ligands, rigid ligands, such as 1,4-benzenedicarboxylate, are widely employed as spacer linkers (Eddaoudi *et al.*, 2001). Recently, flexible ligands have been used to construct coordination polymers because they may induce some unusual structures (Burrows *et al.*, 2004; Li *et al.*, 2004). However, ligands with both rigidity and flexibility are seldom used to assemble coordination polymers. For example, an *N*-substituted aromatic amide has rigidity owing to the amide group ( $-\text{CO}-\text{N}-$ ) conjugating with the aromatic ring, while the  $\sigma$ -rotation about the  $\text{N}-\text{C}$  bond could induce flexibility in the molecule. Moreover, the imine group  $\text{N}=\text{H}$  could serve as a better hydrogen-bonding donor and the amide  $\text{C}=\text{O}$  could also act as a better hydrogen-bonding acceptor (Manoj & Vijayan, 2000). Therefore, we have designed and synthesized a semi-flexible amide ligand, 2,2'-[1,4-bis(-benzamido)]diacetic acid ( $\text{H}_2\text{L}$ ), and employed it with  $\text{Zn}^{\text{II}}$  ions to assemble the title coordination polymer, (I).

**Figure 1**

The molecular structure of (I), with displacement ellipsoids at the 25% probability level (arbitrary spheres for H atoms). Dashed lines indicate hydrogen bonds. [Symmetry codes: (i)  $2 - x, y, \frac{3}{2} - z$ ; (vi)  $1 - x, -y, 1 - z$ .]

As shown in Fig. 1, the asymmetric unit of (I) consists of one-half of a ligand dianion, one-half of a  $\text{Zn}^{\text{II}}$  ion, one and a half coordinated water molecules, and one uncoordinated water molecule. The  $\text{Zn}^{\text{II}}$  and O3 atoms are located on a twofold axis. The  $\text{Zn}^{\text{II}}$  atom is coordinated by five O atoms in a trigonal-bipyramidal geometry, with Zn—O distances ranging from 1.981 (3) to 2.183 (2) Å (Table 1). Two carboxyl O atoms, O2 and O2<sup>i</sup> [symmetry code: (i)  $2 - x, y, \frac{3}{2} - z$ ], and one water molecule (O4) occupy the equatorial positions, while two water O atoms, O1 and O1<sup>i</sup>, are located at the axial sites. The axial O1...O1<sup>i</sup> vector is almost perpendicular to the equatorial plane. The C3-amide group is almost coplanar with the benzene ring, while the C1-carboxyl group lies out of the benzamide plane, with a dihedral angle of 74.7 (4)°.

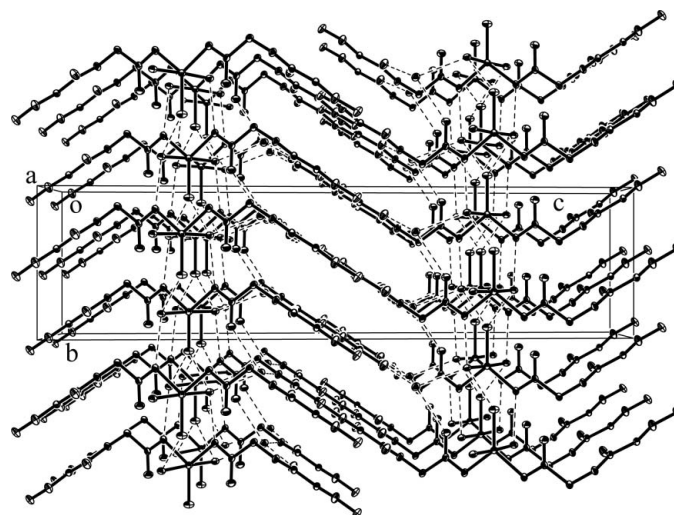

The ligand dianion *L* is located on an inversion center and bridges neighboring  $\text{Zn}^{\text{II}}$  ions to generate one-dimensional zigzag chains propagating along the [201] direction. The small folds near the  $\text{Zn}^{\text{II}}$  ions in the chain can be ascribed to the flexibility arising from rotation about the N—C bond. The C3—N1—C2—C1 torsion angle is  $-72.7$  (4)°.

The dihedral angle between neighboring benzamide planes in the same chain is 68.93 (16)°, and the dihedral angle between the equatorial plane and the benzamide plane is 70.1 (5)°. The Zn...Zn intrachain distance is 16.524 (4) Å, while the Zn...Zn interchain distance is 5.1898 (8) Å.

All chains are arranged in a parallel fashion. The chains are connected by intermolecular hydrogen bonding to form the three-dimensional supramolecular structure (Fig. 2). The shortest centroid—centroid distance of 5.189 (3) Å between parallel phenyl rings from neighboring chains indicates no  $\pi$ — $\pi$  stacking interaction (Janiak, 2000). Atom H1A is involved in a three-centered hydrogen bond (Table 2).

## Experimental

The ligand *L* was synthesized from terephthaloyl chloride and glycine according to a similar method reported by Yuan *et al.* (2002). *L* (28.0 mg, 0.1 mmol) was dissolved in an aqueous solution (10 ml) of  $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 4\text{H}_2\text{O}$  (22.0 mg, 0.1 mmol). The resulting colorless solution was filtered and the filtrate was left at room temperature. Colorless platelet crystals of (I) were obtained (20.1 mg, yield *ca* 46%) after several weeks by slow evaporation of the solvent.

**Figure 2**

A packing diagram of (I), viewed down the *a* axis. All H atoms have been omitted for clarity. Dashed lines indicate hydrogen bonds.

## Crystal data

## Refinement

Refinement on  $F^2$   
 $R[F^2 > 2\sigma(F^2)] = 0.042$   
 $wR(F^2) = 0.120$   
 $S = 1.12$   
 1587 reflections  
 122 parameters  
 H atoms treated by a mixture of independent and constrained refinement

$w = 1/[\sigma^2(F_o^2) + (0.0961P)^2 + 4.1191P]$   
 where  $P = (F_o^2 + 2F_c^2)/3$   
 $(\Delta/\sigma)_{\text{max}} < 0.001$   
 $\Delta\rho_{\text{max}} = 0.41$  e Å<sup>-3</sup>  
 $\Delta\rho_{\text{min}} = -0.62$  e Å<sup>-3</sup>

**Table 1**

Selected geometric parameters (Å, °).

Zn—O1	2.183 (2)	Zn—O4	1.981 (3)
Zn—O2	1.988 (2)		
O4—Zn—O2	127.17 (7)	O2 <sup>i</sup> —Zn—O1	88.65 (9)
O2 <sup>i</sup> —Zn—O2	105.65 (13)	O2—Zn—O1	92.41 (9)
O4—Zn—O1	89.12 (6)	O1—Zn—O1 <sup>i</sup>	178.24 (11)

Symmetry code: (i)  $-x + 2, y, -z + \frac{3}{2}$ .

Table 2

Hydrogen-bond geometry (Å, °).

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
O1–H1A $\cdots$ O2 <sup>ii</sup>	0.85	1.93	2.772 (3)	170
O1–H1B $\cdots$ O6 <sup>iii</sup>	0.85	1.93	2.744 (4)	161
N1–H3 $\cdots$ O6	0.86	2.15	2.913 (4)	148
O4–H4 $\cdots$ O1 <sup>ii</sup>	0.84 (2)	1.95 (2)	2.771 (3)	165 (3)
O6–H6A $\cdots$ O5 <sup>iv</sup>	0.85	1.91	2.747 (3)	167
O6–H6B $\cdots$ O3 <sup>v</sup>	0.85	1.97	2.738 (3)	149

Symmetry codes: (ii)  $-x + \frac{3}{2}, y - \frac{1}{2}, -z + \frac{3}{2}$ ; (iii)  $-x + 1, y, -z + \frac{3}{2}$ ; (iv)  $x - 1, y, z$ ; (v)  $x - \frac{1}{2}, y + \frac{1}{2}, z$ .

H atoms of the O1 and O6 water molecules were located in a difference Fourier map, idealized, and refined as riding, with O–H = 0.85 Å. Atom H4 was located in a difference Fourier map and refined subject to an O–H restraint of 0.85 (3) Å and an H $\cdots$ H restraint of 1.385 (3) Å. Other H atoms were placed at calculated positions, with C–H = 0.93 Å (aromatic) and 0.97 Å (methylene), and N–H = 0.86 Å, and refined using a riding model. In all cases, the  $U_{iso}(H)$  value is 1.2 times  $U_{eq}$  of the parent atom.

Data collection: *CAD-4 Software* (Enraf–Nonius, 1989); cell refinement: *CAD-4 Software*; data reduction: *XCAD4* (Harms & Wocadlo, 1995); program(s) used to solve structure: *SHELXS97* (Sheldrick, 1997); program(s) used to refine structure: *SHELXL97* (Sheldrick, 1997); molecular graphics: *SHELXTL* (Sheldrick, 2000); software used to prepare material for publication: *SHELXTL*.
