The molecules of the title compound, $C_{11}H_{11}NOS_2$, form hydrogen-bonded dimers in the solid state. The amide H atom serves as hydrogen-bond donor and the thiocarbonyl S atom of a neighbouring molecule serves as acceptor. The *p*-methoxyphenyl substituent is tilted by $7.3(5)^\circ$ from the thiazole-2(3H)-thione plane.

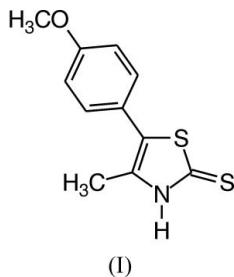

Comment

5-(*p*-Methoxyphenyl)-4-methylthiazole-2(3H)-thione, (I), is formed as a minor product in the photochemical reaction between *N*-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione and Bu_3SnH (Hartung, Gottwald *et al.*, 2005). The identity of compound (I) was established by X-ray diffraction analysis.

Key indicators

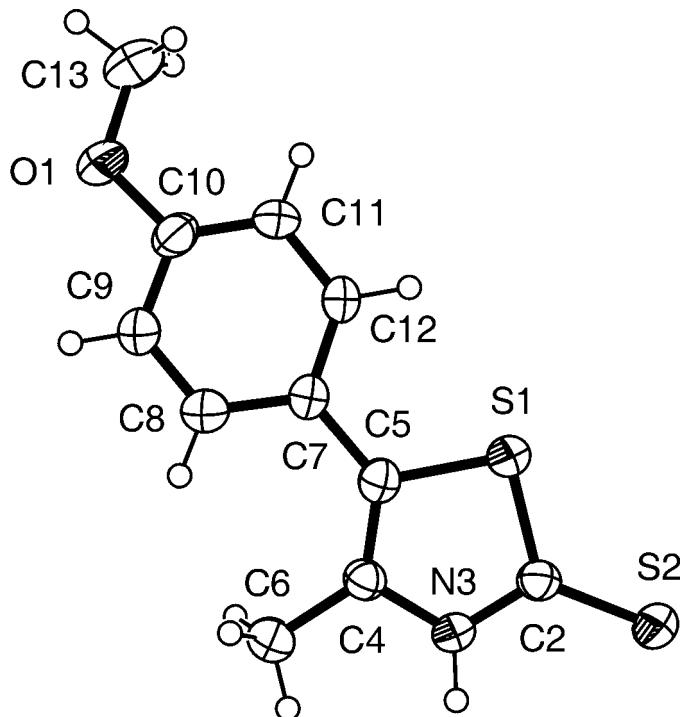

Single-crystal X-ray study
 $T = 299\text{ K}$
Mean $\sigma(C-C) = 0.005\text{ \AA}$
 R factor = 0.041
 wR factor = 0.088
Data-to-parameter ratio = 15.9

For details of how these key indicators were automatically derived from the article, see <http://journals.iucr.org/e>.

(I)

The methoxy group is situated in the plane of the aryl substituent, presumably for reasons of maximum overlap between one of the non-bonding electron pairs of oxygen and the aromatic π -system [$C11-C10-O1-C13 = 5.0(5)^\circ$]. The *p*-methoxyphenyl substituent is tilted by $C4-C5-C7-C8 = 7.3(5)^\circ$ from the thiazole-2(3H)-thione plane defined by atoms S1, C2, N3, C4 and C5 [deviation of $0.002(7)\text{ \AA}$ for atom C2 and $0.009(7)\text{ \AA}$ for N3] (Fig. 1). This value is significantly smaller than the corresponding dihedral angle in both *N*-benzoyloxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione [$51.6(3)^\circ$; Hartung, Altermann *et al.*, 2005] and *N*-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione [$51.8(4)^\circ$; Hartung, Špehar *et al.*, 2005]. The $C2-S2$ bond length in (I) [$1.679(3)\text{ \AA}$] is comparable to the $C=S$ distance in, for example, *N*-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione [$1.676(3)\text{ \AA}$], *N*-isopropoxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione [$1.659(2)\text{ \AA}$] and *N*-pentoxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3H)-thione [$1.671(7)\text{ \AA}$; Hartung, Gottwald *et al.*, 2005]. The bond lengths within the heterocyclic core increase along the series $C2-N3 = 1.340(3)\text{ \AA} < C4-C5 = 1.347(4)\text{ \AA} < C4-N3 = 1.390(3)\text{ \AA} < C2-S2 = 1.679(3)\text{ \AA} < C2-S1 = 1.720(3)\text{ \AA} < C5-S1 = 1.758(3)\text{ \AA}$. The endocyclic bond angles of the 1,3-thiazolidine subunit (Table 1) are, within

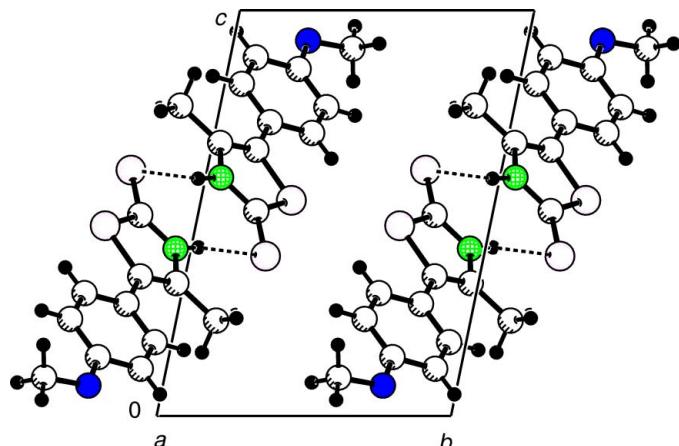

**Figure 1**

The molecular structure of (I). Displacement ellipsoids are drawn at the 50% probability level.

experimental error, identical to the values reported for *N*-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione (Hartung, Špehar *et al.*, 2005). An intermolecular N—H···S hydrogen bond links the molecules into hydrogen-bonded dimers (Fig. 2), where the amide H atom serves as hydrogen-bond donor and the thiocarbonyl S atom of a neighbouring molecule serves as an acceptor (Table 2). This type of hydrogen bonding is usual for heterocyclic thioamides (Penfold, 1953; Reynolds *et al.*, 1995; Nalini & Desiraju, 1987; Polonski *et al.*, 1999; Linden *et al.*, 2001; Kunimoto *et al.*, 2002; Zhong *et al.*, 2003).

Experimental

A solution of *N*-hydroxy-5-(*p*-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione (96.0 mg, 0.36 mmol) (Hartung *et al.*, 2003) and Bu₃SnH (103.3 mg, 0.36 mmol) in anhydrous C₆H₆ (5 ml) was photolyzed ($\lambda = 350$ nm) for 10 min under Ar (293 K). The solvent was evaporated under reduced pressure. The residue was purified by column chromatography (SiO₂, petroleum ether/acetone 2:1 *v/v*) to afford 5-(*p*-methoxyphenyl)-4-methyl-2-(tributylstannylsulfanyl)thiazole (129 mg, 68%) (Hartung, Gottwald *et al.*, 2005) and 5-(*p*-methoxyphenyl)-4-methylthiazole-2(3*H*)-thione, (I) (20.5 mg, 24%). Compound (I) crystallizes from MeOH as pale yellow plates, which were suitable for X-ray diffraction. Analysis calculated for C₁₁H₁₁NOS₂: C 55.67, H 4.67, N 5.90, S 27.02%; found C 55.43, H 4.51, N 5.75, S 26.13%. MS (EI, 70 eV), *m/z* (%) = 237 [M⁺, (100)], 222 (17), 178 (5), 163 (14). HR MS: calculated 237.0282, found 237.0282. ¹H NMR (CDCl₃, 250 MHz) δ_H = 2.31 (*s*, 3H), 3.84 (*s*, 3H), 6.94 (Ar-*d*, 2H, $J = 8.6$ Hz), 7.25 (Ar-*d*, 2H, $J = 8.6$ Hz). ¹³C NMR (CDCl₃, 63 MHz) δ_C = 33.7, 36.6, 55.4, 114.4, 130.0, 159.8, 171.5. UV/Vis (CH₃CN): λ (log ε) = 284 nm (4.23 *sh*).

Symmetry code: (i) $-x, 2-y, 1-z$.

Atom H3 was located in a difference Fourier map. The atomic coordinates of H3 were refined with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{N}3)$. All other H atoms were positioned geometrically and treated as riding atoms ($\text{C}-\text{H} = 0.93\text{--}0.96 \text{\AA}$), with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$.
