## tert-Butyl 4,4-dimethyl-5-oxo-1,3-oxazolidine-3-carboxylate

In the title compound, $\mathrm{C}_{10} \mathrm{H}_{17} \mathrm{NO}_{4}$, the urethane group is planar and the oxazolidinone ring adopts an envelope conformation. Intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions link the screw- and glide-related molecules into a two-dimensional network parallel to (101).

## Comment

N -Methylamino acid-containing peptides are increasingly recognized as potentially useful therapeutics (Fairlie et al., 1995). $N$-Methylation has been shown to improve pharmacokinetically useful parameters, such as membrane permeability, proteolytic stability and conformational rigidity (Cody et al., 1997). $N$-Methylamino acids are useful for obtaining information about the backbone conformations and structureactivity relationships of peptides. $\mathrm{N}^{\alpha}$-Urethane-protected 5oxazolidinones are key intermediates, serving as useful synthons in the synthesis of $N$-methylamino acids (Freidinger et al., 1983). They are also utilized for the direct preparation of dipeptides containing N -methylamino acids (Dorow \& Gingrich, 1999) and for the synthesis of angiotensin-II analogues with full agonistic activity at the AT receptor (Johannesson et al., 1999, 2002). $\alpha$-Aminoisobutyric acid (Aib) is an unusual amino acid, in which the $\alpha$ - H atom of L -alanine is replaced by a methyl group. This substitution makes the residue achiral and introduces severe stereochemical constraints. Several Aib-containing microbial peptides (e.g. alamethacin, zervamicin, emerimicin, etc.) possess the ability to modify the permeability properties of phospholipid bilayer membranes and also form transmembrane channels. Bocamino acids and peptides are often used as substrates, substrate analogues or competitive inhibitors of proteolytic enzymes (Benedetti et al., 1980). We report here the crystal structure of the title compound, (I).

(I)

In the Boc group, the tert-butyl group is staggered with respect to the $\mathrm{O} 1-\mathrm{C} 5$ bond (Fig. 1). The torsion angles $\mathrm{C} 5-$ $\mathrm{O} 1-\mathrm{C} 4-\mathrm{C} 1\left[59.3(1)^{\circ}\right], \mathrm{C} 5-\mathrm{O} 1-\mathrm{C} 4-\mathrm{C} 2\left[176.8(1)^{\circ}\right]$ and $\mathrm{C} 5-\mathrm{O} 1-\mathrm{C} 4-\mathrm{C} 3\left[-65.4(1)^{\circ}\right]$ are close to the ideal values of 60,180 and $-60^{\circ}$, respectively. The torsion angle $\mathrm{C} 4-\mathrm{O} 1-$ $\mathrm{C} 5-\mathrm{O} 2\left[4.7(2)^{\circ}\right]$ indicates that the $\mathrm{C} 4-\mathrm{O} 1$ and $\mathrm{C} 5-\mathrm{O} 2$ bonds are in a cis conformation. The bond angle $\mathrm{O} 1-\mathrm{C} 4-\mathrm{C} 2$ [101.6 (1) $)^{\circ}$ ] is smaller while $\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 1\left[112.4(1)^{\circ}\right]$ is larger

than the tetrahedral value. The $\mathrm{C} 4-\mathrm{O} 1-\mathrm{C} 5$ angle is $121.2(1)^{\circ}$ and it deviates from the usual value of $116.0^{\circ}$ observed in ester groups (Karlsson et al., 1979). These deviations are mainly due to the non-bonded repulsion between O 2 and two of the methyl groups ( C 1 and C 3 ) in the Boc moiety (Marsh et al., 1977).

The urethane group is planar and the angle $\mathrm{O} 1-\mathrm{C} 5-\mathrm{N} 1$ [111.4 (1) ${ }^{\circ}$ ] is lower by about $5.2^{\circ}$ than the corresponding value (116.6 ${ }^{\circ}$; Benedetti et al., 1980) observed in trans peptides. This is because the repulsion between the trigonal O atom in the urethane and the nearest substituent on the N 1 atom is smaller than the corresponding repulsion between the tetrahedral $\mathrm{C}^{\alpha}$ atom in the peptide group and the nearest substituent on the peptide N atom. The $\mathrm{N} 1-\mathrm{C} 5-\mathrm{O} 1-\mathrm{C} 4$ and $\mathrm{O} 1-\mathrm{C} 5-\mathrm{N} 1-\mathrm{C} 6$ torsion angles are $-175.42(8)-2.9(1)^{\circ}$, respectively.

The atom C6 deviates by 0.134 (1) $\AA$ from the mean plane through atoms C9/O4/C10/N1. The puckering parameters (Cremer \& Pople, 1975) and smallest displacement asymmetry parameters (Nardelli, 1983) for the ring (involving atoms C9/ $\mathrm{O} 4 / \mathrm{C} 10 / \mathrm{N} 1 / \mathrm{C} 6), q 2=0.082(1) \AA, \varphi=146.3(1)^{\circ}$ and $\Delta_{\mathrm{s}}(\mathrm{C} 6)=$ 0.003 (1), show that it adopts an envelope conformation, with flap atom C6. The molecular structure is stabilized by three $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ intramolecular interactions. The crystal packing is stabilized by two $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ intermolecular interactions (Table 2). The $\mathrm{C} 10-\mathrm{H} 10 B \cdots \mathrm{O} 2^{\mathrm{ii}}$ interaction links screwrelated molecules into chains along the $b$ axis. Glide-related molecules in adjacent chains are linked by intermolecular $\mathrm{C} 2-\mathrm{H} 2 C \cdots \mathrm{O} 3^{\mathrm{i}}$ interactions (symmetry codes are given in Table 2), forming a two-dimensional network parallel to (101) (Fig. 2).

## Experimental

A slurry of tert-butoxycarbonylisobutyric acid $(2.033 \mathrm{~g}, 10 \mathrm{mmol})$, paraformaldehyde $(2 \mathrm{~g})$ and $p$-toluenesulfonic acid ( 100 mg , 0.52 mmol ) in toluene ( 5 ml ) was exposed to microwave irradiation. The reaction mixture was diluted with ethyl acetate ( 15 ml ), washed with water $(2 \times 10 \mathrm{ml})$, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and concentrated under reduced pressure. The resulting residue was recrystallized using dichloromethane and hexane (1:3 $\mathrm{v} / \mathrm{v}$ ) [yield: 1.65 g
