## Bis(diphenylphosphinato- $\kappa$ O)bis(diphenylphosphinic acid- $\kappa$ O)bis(pyridine- $\kappa N$ )mercury(II)

In the centrosymmetric molecule of the title compound, $\left[\mathrm{Hg}\left(\mathrm{C}_{12} \mathrm{H}_{10} \mathrm{O}_{2} \mathrm{P}\right)_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)_{2}\left(\mathrm{C}_{12} \mathrm{H}_{11} \mathrm{O}_{2} \mathrm{P}\right)_{2}\right]$, the approximately octahedral Hg atom is coordinated by two each of phenylphosphinate, phosphinic acid and pyridine ligands. Each pair of phosphinic acid and phosphinate ligands features an intramolecular hydrogen bond, so forming an eight-membered ring.

## Comment

The ability of phosphinate ligands to promote the formation of bridged coordination polymers (Vioux et al., 2004) prompted us to study its mercury compounds (Siqueira et al., 2006). In the course of crystallization, one sample had crystals in the form of blocks, instead of the usual needle morphology characteristic of the coordination polymer catena- $[\mathrm{Hg}(\mu$ $\left.\mathrm{O}_{2} \mathrm{PPh}_{2}\right)_{2}\left(\mathrm{NC}_{5} \mathrm{H}_{5}\right)_{2}$ ]. A single-crystal X-ray study of the crystals revealed that the title compound, (I), had formed. This phenomenon has been reported for the $\mathrm{Mn}^{\mathrm{II}}$ complex of phenylphosphinic acid (Betz \& Bino, 1988).

(I)

One half-molecule of (I) is found in the asymmetric unit; the complete molecule is generated by the crystallographic centre of inversion coincident with the Hg atom (Fig. 1). The approximately octahedral coordination around the Hg atom is formed by four equatorial O atoms from the mono-coordinate diphenylphosphinate and diphenylphosphinic acid ligands and two axial N atoms of the pyridine ligands. The $\mathrm{Hg}-\mathrm{O}$ and $\mathrm{Hg}-\mathrm{N}$ distances are similar to those of the previously reported polymeric species, in which they are 2.529 (3) and 2.190 (3) A, respectively. The much longer $\mathrm{Hg}-\mathrm{O}$ bond can be attributed to the coordinating anion nature of the diphenylphosphinate ligand, where the $\mathrm{Hg}-\mathrm{O}$ bonds are

Received 27 January 2006
Accepted 14 March 2006

Figure 1
The structure of (I), showing the atom-numbering scheme and with displacement ellipsoids drawn at the $50 \%$ probability level. The symmetry-equivalent C atoms are shown as grey lines. Hydrogen bonds are shown as dashed lines, and H atoms not involved in hydrogen bonding have been omitted. [Symmetry code: (i) $-x,-y,-z+1$.]
formed largely by electrostatic attraction. The angles around the Hg centre show a variation from ideal, due to the tilt of $78.68(9)^{\circ}$ between the equatorial plane of the Hg and O atoms and the line formed by the two axial N atoms.

An intramolecular hydrogen bond between the diphenylphosphinate and the diphenylphosphinic acid ligands presumably stabilizes the formation of the molecular compound by the formation of an eight-membered ring. For both diphenylphosphinate and diphenylphosphinic acid ligands, the $\mathrm{P}-\mathrm{O}$ distance for the O atom bound to the metal center is shorter than that to the free O atom. This indicates that both ligands have the predominant character $\mathrm{O}=\mathrm{P}-\mathrm{O}$ where, contrary to expectations, the doubly bonded O atom of the diphenylphosphinate ligand binds to the Hg centre. The localization of the formal negative charge on the free O atom can be attributed to the strong hydrogen bonding in which the atom participates. The previously reported compound $\left.\left[\mathrm{Mn}\left(\mathrm{O}_{2} \mathrm{PPh}_{2}\right)_{2}\left(\mathrm{HO}_{2} \mathrm{PPh}_{2}\right)_{2}\right)_{2}\left(\mathrm{OCN}\left(\mathrm{CH}_{3}\right)_{2}\right)_{2}\right]$ (Betz \& Bino, 1988) has a very similar geometry.

## Experimental

Crystals of (I) formed by the slow evaporation of a solution of $\left[\mathrm{Hg}\left(\mathrm{O}_{2} \mathrm{PPh}_{2}\right)_{2}\right]$ in a mixture of dimethylformamide-pyridinemethanol (1:1:1 $\mathrm{v} / \mathrm{v} / \mathrm{v}$ ).

All H atoms were found in a difference Fourier map before being repositioned geometrically and refined using a riding model, with $\mathrm{C}-$ $\mathrm{H}=0.95 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ for the H atoms of the pyridine and phenyl rings, and $\mathrm{O}-\mathrm{H}=0.84 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$ for the H atom on the diphenylphosphinic acid ligand. The highest residual electron-density peak is $1.27 \AA$ from Hg and the deepest hole is $0.88 \AA$ from the Hg atom. None of the largest peaks is chemically sensible and they are likely to be absorption artifacts.

Data collection: COLLECT (Nonius, 2000); cell refinement: SCALEPACK (Otwinowski \& Minor, 1997); data reduction: DENZO (Otwinowski \& Minor, 1997) and SCALEPACK; program(s) used to solve structure: SHELXS97 (Sheldrick, 1997); program(s) used to refine structure: SHELXL97 (Sheldrick, 1997); molecular graphics: DIAMOND (Crystal Impact, 2005); software used to prepare material for publication: WinGX (Farrugia, 1999).

## metal-organic papers

Financial support from the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) (grant Nos. 478831/2003-0 and 475294/2004-1) and the Coordenação de Aperfeiçoamento de Pessoa de Nível Superior (CAPES) is gratefully acknowledged, as are fellowships (RAB and MRS) from CNPq. The diffractometer was funded by a CT-INFRA grant from the Financiadora de Estudos e Projetos (FINEP).
