Key indicators

Single-crystal X-ray study
 $T = 100$ K
Mean $\sigma(\text{C}-\text{C}) = 0.004$ Å
 R factor = 0.025
 wR factor = 0.064
Data-to-parameter ratio = 21.8For details of how these key indicators were
automatically derived from the article, see
<http://journals.iucr.org/e>.Di- μ_2 -chloro-bis[(benzylidiphenylphosphine)-
chloropalladium(II)]

The molecule of the title compound, $[\text{Pd}_2\text{Cl}_4(\text{C}_{19}\text{H}_{17}\text{P})_2]$ or $[\text{Pd}(\mu_2\text{-Cl})\text{Cl}(\text{PPh}_2\text{Bz})]_2$, where $\text{Bz} = \text{CH}_2\text{Ph}$, lies on an inversion centre. The Pd atom has a distorted square-planar coordination environment formed by a benzylidiphenylphosphine [$\text{Pd}-\text{P} = 2.2218$ (6) Å], a terminal chloride [$\text{Pd}-\text{Cl} = 2.2729$ (5) Å] and two bridging chloride ligands. The Pd-Cl bond in the position *trans* to the phosphine ligand [$\text{Pd}-\text{Cl} = 2.4123$ (5) Å] is considerably longer than the Pd-Cl bond in the position *trans* to the terminal chloride [$\text{Pd}-\text{Cl} = 2.3155$ (5) Å].

Comment

Palladium complexes have become the most popular organometallics used in organic synthesis as a result of their remarkable catalytic potential and their versatility. In particular, most of the carbon-carbon bond-forming reactions, such as the Heck reaction, the Stille reaction and the Suzuki reaction, are palladium-catalysed (Bedford *et al.*, 2004). The general class of $[\text{Pd}(\mu_2\text{-Cl})\text{ClP}]_2$ (P = phosphine ligand) complexes has been known since the early studies of Mann and co-workers (Mann & Purdie, 1935; Mann & Wells, 1938). The title complex, (I), was isolated as a side-product in the synthesis of the bisphosphine-palladium complex $[\text{PdCl}_2(\text{PBzPh}_2)]$ ($\text{Bz} = \text{CH}_2\text{Ph}$).

In contrast to the numerous crystallographic characterizations of $[\text{PdCl}_2\text{P}_2]$ complexes, those of $[\text{Pd}(\mu_2\text{-Cl})\text{ClP}]_2$ compounds are sparse. In the crystal structure of (I) (Fig. 1), the dimeric molecule of the complex, $[\text{Pd}(\mu_2\text{-Cl})\text{Cl}(\text{PPh}_2\text{Bz})]_2$, is located around an inversion centre. The structures of a range of related palladium complexes have been determined (Chaloner *et al.*, 1995; Coles *et al.*, 1999; Grigsby & Nicholson, 1992; Sui-Seng *et al.*, 2003*a,b*; Vicente *et al.*, 1997; Zoufalá *et al.*, 2004), all presenting virtually the same structural parameters (Table 3) as those of the complex reported here.

The structure of (I) consists of a centrosymmetric dinuclear complex in which each Pd atom exists in a square-planar geometry formed from a terminal chloride, a phosphine and two bridging chloride ligands. These bridging anions form almost orthogonal bonds [$\text{Cl1}-\text{Pd}-\text{Cl1}' = 85.544$ (18)°] to the palladium centres. The bridging Pd-Cl bond distances are asymmetric, with the longer bonds lying opposite the more strongly *trans*-influencing phosphine ligand (Table 3). Some

weak interactions were observed, as reported in Table 2.

The most widely used method for determining ligand steric behaviour at a metal centre is the calculation of the Tolman cone angle (θ_T), as described previously by Tolman (1977) and Otto *et al.* (2000). For the current study, actual Pd–P bond distances were used, with a van der Waals radius of 1.20 Å for H, yielding effective cone angles (θ_E). The substituents of the phosphine may have different orientations, resulting in variations in cone angle sizes, as observed by Ferguson *et al.* (1978), and may not necessarily be a true indication of the steric properties of the phosphine in solution. The value of 172° obtained for benzyldiphenylphosphine is larger than the 148° cone angle obtained for triphenylphosphine (data extracted and calculated from the Cambridge Structural Database; Version 5.27, update of January 2006; Allen, 2002).

Experimental

The title compound was isolated as a side-product of the reaction of [PdCl₂(COD)] with benzyldiphenylphosphine. Dichloro(1,5-cyclooctadiene)palladium(II), [PdCl₂(COD)], was prepared according to the literature procedure of Drew & Doyle (1990). A solution of benzyldiphenylphosphine (55 mg, 0.2 mmol) in dichloromethane (2.0 ml) was added to a solution of [PdCl₂(COD)] (29 mg, 0.1 mmol) in dichloromethane (3.0 ml). The solvent was evaporated and the remaining yellow residue was washed with pentane (2.0 ml). Crystallization from toluene gave a small amount of red crystalline compound (I), as well as nearly quantitative amounts of yellow crystalline *trans*-[PdCl₂(PPh₂Bz)].
