## Key indicators

Single-crystal X-ray study
$T=180 \mathrm{~K}$
Mean $\sigma(\mathrm{C}-\mathrm{C})=0.009 \AA$
Disorder in solvent or counterion
$R$ factor $=0.069$
$w R$ factor $=0.165$
Data-to-parameter ratio $=15.8$
For details of how these key indicators were automatically derived from the article, see http://journals.iucr.org/e.

[^0]The title compound, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]_{3}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{4} \mathrm{~S}\right)_{8} \mathrm{Cl} \cdot 13 \mathrm{H}_{2} \mathrm{O}$, contains one and a half hexamminecobalt(III) cations, four 4-hydroxybenzenesulfonate anions, one half chloride anion and six and a half water molecules in its asymmetric unit. One $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cation lies on a centre of inversion. The $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations and 4-hydroxybenzenesulfonate anions are linked by $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds into 'triple-stranded ribbons'. The chloride anion is disordered in sites between these ribbons.

## Comment

We and others have reported previously the crystal structures of some hexaamminecobalt(III) salts with organic sulfonate anions (Dalrymple et al., 2002; Reddy et al., 2003; Sharma et al., 2004). In continuation of this work, we describe here the crystal structure of the title compound, hexaammine-cobalt(III)-4-hydroxybenzenesulfonate-chloride-water (3/8/ 1/13), (I), containing 4-hydroxybenzenesulfonate counter-ions (Fig. 1).

(I)

There are two distinct $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations in (I) (Table 1), with atom Co1 occupying an inversion centre. The cations are

Figure 1
Structural components of (I), showing displacement ellipsoids at the $50 \%$ probability level. H atoms have been omitted. [Symmetry code: (i) $1-x$, $1-y, 1-z$.]

Received 4 July 2006 Accepted 31 July 2006

Figure 2
Projection of (I) along $b$, showing the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations lying with one of their $C_{4}$ axes approximately perpendicular to (001). A 'triple-stranded ribbon' is enclosed within the central rectangular box. H atoms have been omitted. [Symmetry code: (i) $1-x, 1-y, 1-z$.]
arranged into layers parallel to (001), with one of their $C_{4}$ axes lying approximately perpendicular to the plane of the layers. The 4-hydroxybenzenesulfonate anions lie between these layers with their long axes also oriented approximately perpendicular to the layer plane. Viewed in projection along the $b$ direction (Fig. 2), groups of three $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations can be distinguished within a (001) layer. Thus, the structure of (I) can be described in terms of 'triple-stranded ribbons' of stoichiometry $\left\{\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]_{3}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SO}_{4}\right)_{8}\right\}^{+}$. Four crystallographically distinct 4-hydroxybenzenesulfonate anions are present. In two of these (containing S2 and S4), the $\mathrm{C}-\mathrm{S}$ bond of the sulfonate unit lies approximately parallel to the $C_{4}$ axes of the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations. In two others (containing S1 and S 3 ), the $\mathrm{C}-\mathrm{S}$ bonds form small angles to the $C_{4}$ axes.

The hydrogen-bonding interactions between the cations and anions (Table 2) comprise an assortment of vertex-to-face and edge-to-face arrangements. In the former, one $\mathrm{S}-\mathrm{O}$ bond of the sulfonate anion is directed approximately towards the centroid of one $\left(\mathrm{NH}_{3}\right)_{3}$ face of the octahedral $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cation, so that the O atom at the vertex of the tetrahedral sulfonate anion accepts hydrogen bonds from all three $\mathrm{NH}_{3}$ groups. In the edge-to-face arrangement, one $\mathrm{O} \cdots \mathrm{O}$ edge of the sulfonate unit lies across one $\left(\mathrm{NH}_{3}\right)_{3}$ face of the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cation, so that one O atom accepts a hydrogen bond from one $\mathrm{NH}_{3}$ group and the other O atom lies over the mid-point of the opposite $\mathrm{NH}_{3} \cdots \mathrm{NH}_{3}$ edge, accepting hydrogen bonds from both $\mathrm{NH}_{3}$ groups. In the two (equivalent) outer strands of each triple-ribbon, the 4-hydroxybenzenesulfonate anion containing S3 forms two edge-to-face interactions on one side of the ribbon. On the other side, S4 forms one edge-to-face interaction and one vertex-to-face interaction in which the $\mathrm{S} 4-\mathrm{O} 42$ bond lies parallel to the direction of propagation of the chains. The central (Co1) strand in the triple-ribbons is linked to the outer strands through the 4-hydroxybenzenesulfonate anions containing S1

Figure 3
Disordered region of (I), between two triple-stranded ribbons. Atom O5W is always present. Either atoms Cl 1 and $\mathrm{O} 6 W$ (coloured) or atoms $\mathrm{O} 7 W$ and $\mathrm{O} 8 W$ (grey) are present in any one site. Dotted lines denote hydrogen bonds between Cl 1 and $\mathrm{O} 6 W$, and H atoms have been omitted. [Symmetry codes: (iii) $2-x, 1-y, 1-z$; (iv) $2-x, 2-y, 1-z$.]
and S2. These two anions lie on opposite sides of the ribbons and interact in an essentially identical manner: they bridge between two $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ cations, with one $\mathrm{O} \cdots \mathrm{O}$ edge of the sulfonate group forming an edge-to-face interaction, and the opposite O atom forming a vertex-to-face interaction.

The triple-stranded ribbons in (I) are arranged with the hydroxybenzene portions of the 4-hydroxybenzenesulfonate anions interdigitating between them. A complex pattern of additional $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ interactions is formed between the hydroxyl groups, the O atoms of the sulfonate anions and the uncoordinated water molecules. Where the edges of adjacent triple strands meet, regions are formed that are rich in $\mathrm{N}-\mathrm{H}$ hydrogen-bond donors. These regions are occupied by chloride anions. A disordered description of the structure is suggested by refinement of the site-occupancy factor for Cl 1 to 0.52 (1), and is a requirement for overall charge balance. The $\mathrm{Cl}^{-}$anions occupy positions that bridge $\mathrm{NH}_{3} \cdots \mathrm{NH}_{3}$ edges in one triple strand, and bridge between two $\mathrm{NH}_{3}$ vertices of the adjacent triple strand (Fig. 3). The Cl 1 sites are spaced at $c a$ $4 \AA$ intervals along the $b$-axis direction, which does not preclude occupation of all of them in any one channel, i.e. the disorder is not necessarily a result of occupation of only every other Cl 1 site along $b$. Water molecules $\mathrm{O} 5 W$ and $\mathrm{O} 6 W$ (the latter modelled as disordered over two closely spaced sites) lie in suitable positions to bridge between adjacent $\mathrm{Cl}^{-}$anions via $\mathrm{O}-\mathrm{H} \cdots \mathrm{Cl}^{-}$hydrogen bonds.

## Experimental

Hexaamminecobalt(III) chloride $(0.5 \mathrm{~g}, 0.0018 \mathrm{~mol})$ was dissolved in hot water $(15 \mathrm{ml})$ by mechanical stirring. In a second beaker, sodium 4-hydroxybenzenesulfonate dihydrate $(1.3 \mathrm{~g}, \quad 0.0056 \mathrm{~mol})$ was dissolved in hot water $(20 \mathrm{ml})$. These solutions were mixed and allowed to cool slowly to room temperature. After 2 h , orange crystals of (I) were formed, which were filtered and dried in air. The overall yield is quantitative. Elemental analysis is consistent with the composition $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]_{3}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SO}_{4}\right)_{8} \mathrm{Cl} \cdot 13 \mathrm{H}_{2} \mathrm{O}$; found: C 27.30, H 4.40, N 11.81, $\mathrm{Co} 8.20, \mathrm{Cl} 1.62 \%$; calculated: C 27.39, H 5.70, N 11.99, Co 8.40, Cl 1.68\%. IR (KBr, $v, \mathrm{~cm}^{-1}$ ): 3243 (br), 1605 (m), 1324 ( $s$, for coordinated $\mathrm{NH}_{3}$ ) and $1119(s), 1004(s), 693(s$, for sulfonate anions).
${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{D}_{2} \mathrm{O}\right): ~ \delta 6.12-6.15(d, 16 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{D}_{2} \mathrm{O}\right): \delta 159.6$ (1-C), 136.3 (4-C), 129.0 (2,6-C), 116.8 (3,5-C).

Symmetry codes: (i) $-x+1,-y+1,-z+1$; (ii) $-x+2,-y+1,-z+1$; (iii) $x, y-1, z$.

The $\mathrm{C}-$ and N -bound H atoms were positioned geometrically ( $\mathrm{C}-$ $\mathrm{H}=0.95 \AA$ and $\mathrm{N}-\mathrm{H}=0.91 \AA$ ) and refined as riding, with $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\text {eq }}(\mathrm{C})$ or $1.5 U_{\text {eq }}(\mathrm{N})$. The $\mathrm{NH}_{3}$ groups were initially allowed to rotate around each local threefold axis. To assist convergence, this rotation was not allowed in the final cycles of refinement. The hydroxyl H atoms were placed along the $\mathrm{O} \cdots \mathrm{O}$ vector offering the shortest potential hydrogen bond. The H atoms of the uncoordinated water molecules were mostly located in difference Fourier maps. For the disordered $\mathrm{O} 6 \mathrm{~W}, \mathrm{O} 7 W$ and $\mathrm{O} 8 W$ molecules, they were placed so as to form a reasonable hydrogen-bond network, with $\mathrm{O}-\mathrm{H}$ distances of $0.84 \AA$. For the final cycles of refinement, all $\mathrm{O}-\mathrm{H}$ distances were normalized to $0.84 \AA$ and the H atoms were made to ride on their parent O atom, with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$. In a structure as complex as this, the water H atoms positions should be regarded as less certain.

The site-occupancy factor of Cl 1 refined to 0.52 (1), but was subsequently constrained to be $\frac{1}{2}$, since this is required for overall charge balance. Atom $\mathrm{O} 8 W$ is present when Cl 1 is not, so its siteoccupancy factor was also constrained to be 0.5 . One further water molecule was modelled as disordered over two closely spaced sites, O6W and O7W. The site-occupancy factors of these atoms (constrained to sum to unity) were refined to 0.60 (2):0.40 (2). However, both were subsequently constrained to be $\frac{1}{2}$, principally for the reason that this makes the structure conceptually much easier to comprehend: in any particular site, either Cl 1 and O 6 W are present, or O 7 W and O 8 W are present. This moderate approximation is accommodated acceptably by the anisotropic displacement parameters of the atoms concerned.

Data collection: APEX2 (Bruker-Nonius, 2003); cell refinement: SAINT (Bruker, 2003); data reduction: SAINT; program(s) used to solve structure: SHELXTL (Sheldrick, 2000); program(s) used to refine structure: SHELXTL; molecular graphics: SHELXTL; software used to prepare material for publication: SHELXTL.
