Correspondence e-mail: w.harrison@abdn.ac.uk

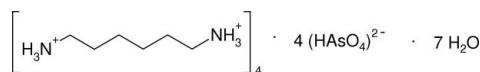

Received 14 May 2007; accepted 14 May 2007

Key indicators: single-crystal X-ray study;  $T = 120\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.006\text{ \AA}$ ; H-atom completeness 85%; disorder in main residue;  $R$  factor = 0.047;  $wR$  factor = 0.126; data-to-parameter ratio = 21.1.

The title compound,  $4\text{C}_6\text{H}_{18}\text{N}_2^{2+} \cdot 4\text{HAsO}_4^{2-} \cdot 7\text{H}_2\text{O}$ , contains a complex network of organic cations, hydrogenarsenate anions and water molecules. One of the two distinct  $(\text{HAsO}_4)^{2-}$  anions shows the expected distinction between protonated and unprotonated As—O bond lengths. The component species interact by way of N—H···O and O—H···O hydrogen bonds, with the latter leading to distinct centrosymmetric  $(\text{HAsO}_4)_4$  tetramers, in which the central linking O—H···O bond is assumed to be disordered about the inversion centre. Together, the cations and anions form an unusual three-dimensional framework encapsulating [100] channels occupied by the water molecules.

## Tetrakis(1,6-hexanediammonium) tetrakis(hydrogenarsenate) heptahydrate

M. J. Todd and W. T. A. Harrison

### Comment

The title compound, (I), was prepared as part of our ongoing studies of hydrogen bonding interactions in the molecular salts of arsenic oxo-anions (Wilkinson & Harrison, 2007a,b). Its asymmetric unit contains two organic cations, two anions and three-and-a-half water molecules (Fig. 1).

The tetrahedral  $(\text{HAs}_1\text{O}_4)^{2-}$  anion in (I) shows the expected distinction (Table 1) between its protonated and unprotonated As—O bond lengths. The situation for the  $(\text{HAs}_2\text{O}_4)^{2-}$  group is less clear cut, and seems to be correlated with disorder of its H atoms (see below). Both  $\text{C}_2\text{H}_{10}\text{N}_2^{2+}$  dications are in their extended conformations with all their backbone torsion angles close to  $180^\circ$ . Three fully occupied (O9, O10, O11) water molecules and one half occupied (O12) water molecule complete the structure. O12 cannot be more than half occupied due to a close  $\text{O}12 \cdots \text{O}12^{\text{xx}}$  ( $\text{xx} = -x, 1 - y, -z$ ) contact of  $2.21$  (1) Å.

As well as Coulombic forces, the component species in (I) interact by way of a network of  $\text{N}—\text{H} \cdots \text{O}$  and  $\text{O}—\text{H} \cdots \text{O}$  hydrogen bonds (Table 2). The  $(\text{HAsO}_4)^{2-}$  units are linked by way of  $\text{O}—\text{H} \cdots \text{O}$  bonds into distinctive, isolated, tetramers (Fig. 2). The complete assembly is generated by inversion, thus the central  $\text{O}5—\text{H}2 \cdots \text{O}5^i$  (see Table 2 for symmetry code) link must be disordered (*i.e.*  $\text{O}5—\text{H}2 \cdots \text{O}5^i + \text{O}5^i—\text{H}2^i \cdots \text{O}5$  bonds) or possibly a symmetric  $\text{O}5 \cdots \text{H}2 \cdots \text{O}5^i$  bond (*i.e.* the H atom occupies the inversion centre (Wilson, 2001)). These possibilities could not be distinguished in the present experiment and a disordered model was assumed. Either of these possibilities necessitates disorder of the H atoms of the As2-hydrogenarsenate group, with one of the  $(\text{HAsO}_4)^{2-}$  moieties directing its H atom elsewhere. The extended As2—O6 bond length suggests that O6 bears the H atom and if so, it makes an  $\text{O}—\text{H} \cdots \text{O}$  link to the disordered O12 water molecule O atom (Fig. 2).

The cations interact with the anion tetramers by way of a large number of  $\text{N}—\text{H} \cdots \text{O}$  bonds (Table 2), with each  $\text{NH}_3^+$  group making three such links, as is typically seen in these systems (Wilkinson & Harrison, 2007a). Unfortunately the H atoms of the water molecules in (I) could not be located in the present study. The disorder of the As2 H atoms and O12 seems to require that at least some of the water H atoms are also disordered, and the situation is too uncertain to allow their geometrical placement with any confidence.

The packing for (I) results in a distinctive structure (Fig. 3) in which hydrogen-bonded (001) sheets of tetrahedral tetramers are bridged by the organic molecules to result in a framework encapsulating [100] channels, which are occupied by the water molecules.

The structure of 1,6-diamminiumhexane bis(dihydrogenarsenate),  $\text{C}_6\text{H}_{18}\text{N}_2 \cdot (\text{H}_2\text{AsO}_4)_2$ , (II), (Wilkinson & Harrison, 2007a), in which the arsenic-containing anion bears two protons, is entirely different to that of (I). In (II), infinite sheets of H-bonded tetrahedra arise and the centrosymmetric cation adopts a *gauche* conformation. Other types of supramolecular networks based on hydrogen bonded organic cations and arsenate tetrahedra are described by Wilkinson & Harrison (2007b).

---

## Experimental

0.5 M Aqueous solutions of 1,6-diaminohexane (10 ml) and arsenic acid (10 ml) were mixed, resulting in a colourless liquid. Aqueous ammonia was then added to the mixture to raise the pH to 11. Colourless slabs of (I) grew as the water slowly evaporated at 298 K.

## Refinement

The highest difference peak is 0.82 Å from As<sub>2</sub>, and the deepest difference hole is 0.62 Å from As<sub>2</sub> perhaps indicating disorder of the (HAsO<sub>4</sub>)<sup>2-</sup> group, but refinements attempting to model this were unstable. The next-highest feature in the final difference map (0.76 e Å<sup>3</sup>) is at the noise level.

H1 was located in a difference map and refined as riding. H2, H3 and the C- and N-bonded hydrogen atoms were placed in idealized positions (O—H = 0.90 Å, C—H = 0.99 Å, N—H = 0.91 Å) and refined as riding with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{carrier})$ .

The H atoms of the water molecules could not be located.

## Figures

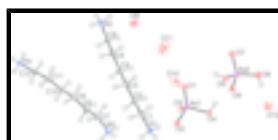

Fig. 1. The molecular structure of (I) (50% displacement ellipsoids; H atoms are drawn as spheres of arbitrary radius).

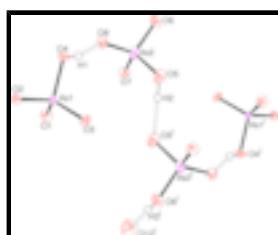

Fig. 2. A tetramer of (HAsO<sub>4</sub>)<sup>2-</sup> tetrahedra in (I) with H bonds indicated by double-dashed lines. Symmetry code as in Table 2. Only one disorder component for H2, H3 and O12 is shown.

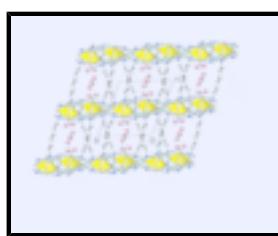

Fig. 3. Unit cell packing in (I) showing the (001) hydrogenarsenate layers bridged by the organic cations, with H bonds indicated by pale blue lines. The water O atoms (pink spheres) occupy [100] channels.

5804 reflections	$(\Delta/\sigma)_{\text{max}} < 0.001$
275 parameters	$\Delta\rho_{\text{max}} = 3.79 \text{ e \AA}^{-3}$
Primary atom site location: structure-invariant direct methods	$\Delta\rho_{\text{min}} = -1.87 \text{ e \AA}^{-3}$
	Extinction correction: none

### Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2\sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
