Received 1 May 2007; accepted 18 May 2007

Key indicators: single-crystal X-ray study; $T=150 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.038 ; w R$ factor $=0.079$; data-to-parameter ratio $=18.7$.

In the title compound, $\mathrm{C}_{11} \mathrm{H}_{11} \mathrm{~N}_{2} \mathrm{~S}_{2}$, there is an intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}[2.778$ (2) $\AA$ ] hydrogen bond linking the quinoline N atom and the imino N atom. The planar quinoline ring system forms an angle of 67.7 (1) ${ }^{\circ}$ with the dithiocarbazate group. Bond angles for both $\mathrm{S}-\mathrm{C}-\mathrm{S}\left[115.66(8)^{\circ}\right]$ and $\mathrm{N}-$ C-S [119.05 (11) ${ }^{\circ}$ ] are comparable with cis-trans S-methyldithiocarbazate but differ from those found in trans-cis $S$ methyldithiocarbazate and trans-cis $S$-benzyldithiocarbazate. This is due to the $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bond that exists only in the cis-trans conformation found for the title compound.

## S-Quinolin-2-ylmethyldithiocarbazate

F. N.-F. How, D. J. Watkin, K. A. Crouse and M. I. M. Tahir

## Comment

There has been considerable work done on the synthesis and characterization of new compounds derived from $S$-methyl and $S$-benzyldithiocarbazate due to the fact that these compounds have donor atoms that chelate with metal ions to form metal complexes with various coordination modes or they can react with carbonyl compounds to yield Schiff bases which may also be multidentate ligands. Most importantly, they and/or their metal complexes are often biologically active. [Crouse et al., 2004; Neelam et al., 2000 \& Tarafder et al., 2002]. Our attempt to synthesize a novel dithiocarbazate ligand was very successful, and eventually led us to the title compound. [Fig. 1.]

The $\mathrm{C}-\mathrm{N}$ bond $[1.3142$ (17) $\AA$ ] has some double-bond character. [1.296 (2) $\AA$ for $S$-2-picolyldithiocarbazate; Crouse et al., 2003] and [1.320 (3) $\AA$ for $S$-benzyldithiocarbazate; Shanmuga Sundara Raj et al., 2000]. The N10—N11 [1.4056 (17) $\AA$ ] is slightly shorter than in cis-trans $S$-methyldithiocarbazate [1.415 (3) $\AA$; Lanfredi et al., 1977] and $S$-2-picolyldithiocarbazate [1.437 (2) Å; Crouse et al., 2003] but comparable with trans-cis Sbenzyldithiocarbazate. [1.406 (3) Å; Shanmuga Sundara Raj et al., 2000]

The $\mathrm{C}=\mathrm{S}$ bond length $[1.6804$ (14) $\AA$ ] agrees well with both literature values of 1.679 (4) $\AA$ (Lanfredi et al., 1977) and 1.678 (3) $\AA$ (Shanmuga Sundara Raj et al., 2000) proposed as an intermediate between a single $[1.82 \AA$ ] and a double bond [1.56 $\AA$ ] character [Sutton, 1965]. This was attributed to delocalization of negative charge over the $\mathrm{C}-\mathrm{N}-\mathrm{N}-\mathrm{C}-\mathrm{S}$ chain, which was generated upon deprotonation of the ligands during coordination.

The conformations of the structures were assigned based on significant differences in the bond angles and not the bond lengths. Bond angles of $\mathrm{S}-\mathrm{C}-\mathrm{S}$ and $\mathrm{N}-\mathrm{C}-\mathrm{S}$ differ significantly for both cis-trans and trans-cis conformations. [Mattes \& Weber, 1980]

The bond angles, S8-C9—S12 [115.66(8) $\left.{ }^{\circ}\right]$ and N10-C9—S8 [119.05(11) $\left.{ }^{\circ}\right]$ are agreeable with cis-trans $S$-methyldithiocarbazate [116.2 (1) ${ }^{\circ}$ and $119.3(1)^{\circ}$; Lanfredi et al., 1977] but was significantly different from trans-cis $S$-methyldithiocarbazate [125.5 (3) ${ }^{\circ}$ and $113.6(3)^{\circ}$; Mattes \& Weber, 1980] and trans-cis $S$-benzyldithiocarbazate [125.5 (2) ${ }^{\circ}$ and $113.5(2)^{\circ}$; Shanmuga Sundara Raj et al., 2000]

The significance of the bond angles is related to the existence of intramolecular hydrogen bonds in both cis-trans and trans-cis conformers. $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds only exists in cis-trans conformer while the trans-cis conformer have N—H.. S hydrogen bonds. [Lanfredi et al., 1977, Mattes \& Weber, 1980 \& Shanmuga Sundara Raj et al., 2000]. The type of hydrogen bonding and the bond angles help differentiate between the types of conformation. Therefore, the title compound is confirmed as cis-trans $S$-quinolin-2ylmethyldithiocarbazate.

The crystal structure consists of layers of aromatic residues lying parallel to the $b c$ plane at $a=0.5$. [Fig. 2.] The dithiocarbazate moieties protrude above and below this plane. Pairs of quinoline rings lie parallel and overlapping with each other (mean separation of $3.4 \AA$ ). This exhibits the characteristic of a $\pi-\pi$ interaction between the rings. [Fig. 3.]

## supplementary materials

There is an intramolecular hydrogen bond N10-H1 $\cdots \mathrm{N} 6\left[2.778(2)^{\circ}\right]$ is slightly shorter than in cis-trans $S$-methyldithiocarbazate. [2.968 (4) ${ }^{\circ}$; Lanfredi et al., 1977], which stabillizes the conformation of the molecule. [Fig. 1.]

The N11—H3 $\cdots$ S 8 contacts could be considered as a weak intermolecular hydrogen bond because the distance of $\mathrm{H} 3 \cdots \mathrm{~S} 8$ is $2.832(1)^{\circ}$, is smaller than the total radii of $\mathrm{H}(1.20)$ and $\mathrm{S}(1.80)$, which is $3.0^{\circ}$ [Fig. 2].

## Experimental

Potassium hydroxide ( 0.2 mol ) was dissolved in $90 \%$ ethanol ( 70 ml ) and mixed with hydrazine hydrate ( 0.2 mol ). The mixture was placed in an ice salt bath to cool to 273 K . Carbon disulfide ( 0.2 mol ) was added dropwise below 265 K with constant stirring over a period of 1 h . Upon addition of carbon disulfide, two layers were formed. $40 \%$ ethanol ( 60 ml ) was added to the brown oil (lower layer) and the mixture was kept in an ice bath. 2-chloromethylquinoline hydrochloride ( 0.2 $\mathrm{mol})$ dissolved in $80 \%$ ethanol $(80 \mathrm{ml})$ was added dropwise with vigorous stirring. The product, cream coloured SQ2MDTC, (I) formed was filtered, recrystallized from ethanol and dried in vacuo over silica gel. (yield 75\%, m.p 414.2-415.7 K). Cystals of SQ2MDTC suitable for X-ray analysis were grown in ethanol through slow evaporation.

## Refinement

The H atoms were all located in a difference map, but those attached to carbon atoms were repositioned geometrically. The H atoms were initially refined with soft restraints on the bond lengths and angles to regularize their geometry ( $\mathrm{C}-\mathrm{H}$ in the range $0.93-0.98, \mathrm{~N}-\mathrm{H}$ in the range $0.86-0.89 \AA$ ) and $U_{\text {iso }}(\mathrm{H})$ (in the range $1.2-1.5$ times $U_{\text {eq }}$ of the parent atom), after which the positions were refined with riding constraints. The other atoms were refined with anisotropic atomic displacement parameters.

## Figures

Fig. 1. The title compound with displacement ellipsoids drawn at the $50 \%$ probability level. H atoms are shown as spheres of arbitary radius. The molecule is stabilized by intramolecular $\mathrm{N}-\mathrm{H}-\mathrm{N}$ hydrogen bond. Dotted line denotes the $\mathrm{N}-\mathrm{H}-\mathrm{N}$ hydrogen bond.

Fig. 2. The packing of the molecule viewed along the $b$ axis showing the aromatic layer lying parallel to the $b c$ plane at $\mathrm{a}=0.5$.

Fig. 3. The stacking $\pi-\pi$ interaction of pairs of the quinoline rings.
