Received 25 June 2007; accepted 3 August 2007

Key indicators: single-crystal X-ray study; $T = 297$ K; mean $\sigma(C-C) = 0.003$ Å; H-atom completeness 85%; disorder in main residue; R factor = 0.046; wR factor = 0.123; data-to-parameter ratio = 13.5.

In the title compound, $[Ni(C_7H_3NO_4)(C_6H_{16}N_2)(H_2O)] \cdot 2.5H_2O$, the discrete neutral $[Ni(dpc)(dien)(H_2O)]$ (dien is diethylenediamine and dpc is dipicolinate) complex lies on a mirror plane. The Ni^{II} ion is coordinated by the dpc ligand through the pyridine N atom and one O atom of each carboxylate group, an aqua ligand and two N atoms of the bidentate dien ligand, forming a distorted octahedral geometry. One of the C atoms of the ethylenediamine group is disordered across the mirror plane. The symmetry-independent ethyl group is disordered over two orientations with equal occupancy. The complex molecules are connected via $O-H\cdots O$ and $N-H\cdots O$ intermolecular hydrogen-bonding interactions.

Aqua(*N,N*-diethylenediamine- κ^2N,N')(pyridine-2,6-dicarboxylato- κ^3N,O,O')nickel(II) 2.5-hydrate

I. Uçar, A. Bulut and C. Kazak

Comment

Pyridine-2,6-dicarboxylic acid, known as dipicolinic acid (H_2dpc), is a versatile ligand and it can function as a neutral, mono basic or dibasic tridentate chelating ligand (Nathan & Mai, 2000; Perry *et al.*, 2004). Having potential donor oxygen and nitrogen atoms, dipicolinic acid has attracted the scientist from the coordination chemistry and number of studies have been carried out with dipicolinate (dpc) ligand by both inorganic and bioinorganic chemists during the past few years (Krillova *et al.*, 2007). Dipicolinates commonly coordinate to transition metals by either carboxylate bridges between metal centres, to form polymeric (Ma *et al.*, 2003) or dimeric complexes (Ramezaniopour *et al.*, 2005), or tridentate (O, N, O') chelation to one metal ion (Okabe & Oya, 2000). The dipicolinate ligand with Ni^{II} ions commonly has one or two coordination modes. In one coordination mode, a single planar dpc ligand binds in the equatorial plane of a Ni^{II} cation and other ligands such as H_2O or pyridine based heterocycles occupy the remaining sites, thereby forming square pyramidal or octahedral coordination geometry (Liu *et al.*, 2006; Zhang *et al.*, 2003), or two planar dpc molecules coordinate perpendicularly generating a distorted octahedral coordination geometry (Park *et al.*, 2007). In our ongoing research on determination of further coordination modes of chelates of dipicolinic acid with biologically important transition metal ions, we have recently synthesized mixed-ligand metal(II) complexes of dipicolinic acid and their structures have been reported (Uçar *et al.*, 2005; Uçar *et al.*, 2007). As a continuation of these studies, we have now prepared and characterized a new Ni^{II} complex containing dipicolinate anion together with diethylenediamine (dien)ligand, namely $[Ni(dien)(dpc)(H_2O)] \cdot 2.5H_2O$.

The asymmetric unit of the title compound consists of one-half of a discrete neutral $[Ni(dien)(dpc)(H_2O)]$ unit and 1.25 lattice water molecules. The $[Ni(dien)(dpc)(H_2O)]$ unit lies across a mirror plane with atoms Ni1, N1, N2, N3, C4 and C5 on the mirror plane. Atom C6 is disordered over two positions across the mirror plane (Fig. 1). The H_2dpc is deprotonated during the reaction and acts as a tridentate ligand. The Ni^{II} ion is six-coordinated in a distorted octahedral geometry, with one N (N3) two O atoms of the tridentate dpc dianion and one N atom from the dien (N1) ligand composing the basal plane, and the aqua O atom and the other N atom (N2) of the dien ligand occupying the axial sites.

The fact that the $Ni1—N_{dpc}$ [1.986 (3) Å] length is significantly shorter than $Ni1—N_{dien}$ [2.070 (3) and 2.122 (3)] bond lengths indicates that atom N3 is the strongest site, because the two carboxylate groups in *ortho* positions enhance the basicity of this atom. The $Ni1—N_{dpc}$, $Ni1—O_{dpc}$ [2.145 (2) Å] and $Ni1—O_{aqua}$ [2.070 (2) Å] bond lengths in the title complex are slightly different from those observed in previously reported mixed-ligand nickel(II) dipicolinate complexes (Ramadevi *et al.*, 2005; Liu *et al.*, 2006; Park *et al.*, 2007). The dpc chelate angle is 77.79 (10)°, which is comparable to that found in other dipicolinate-metal complexes (Chaigneau *et al.*, 2004; Altin *et al.*, 2004).

The crystal packing is stabilized by intermolecular O—H···O and N—H···O hydrogen bonds, involving the oxygen atoms of coordinated and free water molecules (see Table 2 and Fig. 2).

supplementary materials

Experimental

To an ethanol/water (30 ml, 1:1) containing $\text{NiCl}_2 \cdot 4\text{H}_2\text{O}$ (1 mmol) and disodium dipicolinate (1 mmol), dien (1 mmol) was added slowly with continuous stirring. The resulting solution was refluxed for 1 h and then filtered. The green filtrate was allowed to stand for about two weeks at room temperature, after which time light-green crystals of the title compound suitable for X-ray diffraction analysis were collected.

Refinement

Atoms Ni1, N1, N2, N3, C4 and C5 lie on the crystallographic mirror plane. Atom C6 is disordered across the mirror plane and as a result the occupancy factor for the disordered components were fixed at 0.50 each. The independent ethyl group is disordered over two orientations with equal occupancy. The corresponding N—C and C—C distances involving the disorder components were restrained to be equal. In the ethyl group, the components of the displacement parameters in the direction of the bond were restrained to be equal. The displacement parameters of atoms C22A, C23A, C22B, C23B and O4 were restrained to approximate isotropic behaviour. The N1—C6 distance was restrained to 1.45 (1) Å. H atoms of the coordinated water molecule were located in a difference map and refined with O—H and H···H distances restrained to 0.84 (1) and 1.37 (2) Å, respectively. H atoms on O5 and N2 were located in a difference map and refined freely. H atoms on O5 are disordered over two positions. H atoms on one of the free water molecules (O4) could not be located from the difference map. H atoms attached to C atoms were placed at calculated positions ($\text{C}—\text{H} = 0.93\text{--}0.97$ Å) and were allowed to ride on the parent atom [$U_{\text{iso}}(\text{H}) = 1.2\text{--}1.5U_{\text{eq}}(\text{C})$].

Figures

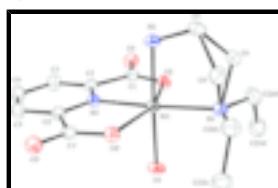

Fig. 1. The structure of $[\text{Ni}(\text{C}_7\text{H}_3\text{NO}_4)(\text{C}_6\text{H}_{16}\text{N}_2)(\text{H}_2\text{O})]$ complex in the title compound. Displacement ellipsoids are drawn at the 30% probability level. Atoms Ni1, N1, N2, N3, C4 and C5 lie on a crystallographic mirror plane. Only one component of the disordered ethyl group is shown. Hydrogen atoms have been omitted for clarity. Symmetry code: (i) $-x, y, z$.

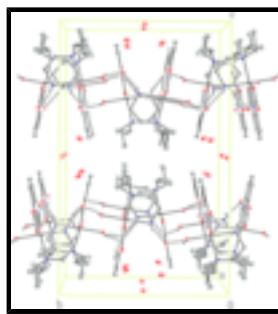

Fig. 2. The crystal packing of the title compound, viewed down the a axis. Hydrogen bonds are shown as dashed lines.

157 parameters	$\Delta\rho_{\text{min}} = -1.12 \text{ e \AA}^{-3}$
38 restraints	Extinction correction: none
Primary atom site location: structure-invariant direct methods	

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

supplementary materials

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
