Received 7 August 2007; accepted 9 August 2007
Key indicators: single-crystal X-ray study; $T=90 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA ; R$ factor $=$ $0.032 ; w R$ factor $=0.085$; data-to-parameter ratio $=7.6$.

Crystals of anhydrous l-aspargine, $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}_{3}$, were obtained from a saturated aqueous solution. The molecules are in their zwitterionic form. Although the carboxyl group is deprotonated, the distances of the two $\mathrm{C} \cdot \mathrm{O}$ bonds are significantly different $[1.2407$ (19) and 1.262 (2) $\AA]$, due to different hydrogen-bond environments. The conformation of the side chain is trans, which distinguishes it significantly from that of L-asparagine monohydrate.

## Related literature

For related literature on single-crystal diffraction studies of L-asparagine monohydrate, see: Arnold et al. (2000); Chandrasekhar et al. (2003); Flaig et al. (2002); Kartha \& de Vries (1961); Ramanadham et al. (1972); Smirnova et al. (1990); Verbist et al. (1972); Wang et al. (1985); Weisinger-Lewin et al. (1989). The unit cell and space group of the title compound were previously determined by powder X-ray diffraction (PDF: 37-1659). For the sample preparation of the title compound, see Yamada et al. (2007). For related literature on crystal structures of l-aspartic acid and its monohydrate, see: Derissen et al. (1968); Umadevi et al. (2003).

## L-Asparagine

K. Yamada, D. Hashizume, T. Shimizu and S. Yokoyama

## Comment

$L$-Asparagine is one of the fundamental natural amino acid residues in proteins. It has been believed that it plays an important role in the formation of the secondary structures in proteins due to the fact that the side chain can form efficient hydrogen bonds with the peptide backbone. In general, amino acids very often have polymorphs. The crystal structures of $L$-asparagine monohydrate (Kartha \& de Vries, 1961; Verbist et al., 1972; Ramanadham et al., 1972; Wang et al., 1985; Weisinger-Lewin et al., 1989; Smirnova et al., 1990; Arnold et al., 2000; Flaig et al., 2002; Chandrasekhar et al., 2003) and D-asparagine monohydrate (Chandrasekhar et al., 2003) have been reported so far. A powder X-ray diffraction study (PDF:37-1659) has been also reported for anhydrous $L$-asparagine. In the present study, a single-crystal structure determination of anhydrous $L$-asparagine, (I), is reported.

The single-crystal diffraction analysis confirms the space group and the unit-cell dimensions previously proposed by the powder diffraction study, and shows that, as expected, the title molecule exists as a zwitter ion in the crystal (Fig. 1). The distances of the $\mathrm{C} \because \mathrm{O}$ bonds in the carboxylate group are significantly different although the group is deprotonated. The corresponding distances are 1.2407 (19) and 1.262 (2) $\AA$ for $\mathrm{C} 2 — \mathrm{O} 1$ and $\mathrm{C} 2 — \mathrm{O} 2$, respectively. The discrepancy is attributed to the number and kind of the intermolecular hydrogen bonds each O atom of the carboxylate participates in. The O 2 atom forms two strong hydrogen bonds with neighboring cationic ammonium groups. O 1 , on the other hand, forms only one relatively weak hydrogen bond with the neutral amide group (Table 2 and Fig. 2). Owing to the formation of two strong hydrogen bonds, the $\mathrm{C} 1-\mathrm{O} 2$ bond is strongly polarized, and the distance of the $\mathrm{C} 1-\mathrm{O} 2$ bond is elongated accordingly. The carbonyl oxygen in the side chain, O3, also forms two hydrogen bonds with each one ammonium and amide group of neighboring molecules.

It is of interest to compare the present structure with that of $L$-asparagine monohydrate (Ramanadham et al., 1972). In the $L$-asparagine monohydrate crystal, the $\mathrm{C} \because \mathrm{O}$ bonds in the ionized carboxyl group are 1.243 and $1.257 \AA$, which is in good agreement with those in (I), but with a slightly less pronounced difference in $\mathrm{C}-\mathrm{O}$ bond lengths. Both oxygen atoms in the monohydrate exhibit each one relatively weak $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond to an amide group, but the oxygen atom with the longer $\mathrm{C}-\mathrm{O}$ distance forms two additional strong H bonds with solvate water molecules. The oxygen atom with the shorter $\mathrm{C}-\mathrm{O}$ bond, on the other hand, forms only one strong hydrogen bond, in this case to the ammonium group. As the difference in the hydrogen bonding environment is thus less pronouced for the monohydrate than in the anhydrous structure this may also explain the more pronounced difference in the $\mathrm{C}-\mathrm{O}$ distances found in the structure of the title compound.

The conformation of the backbone of (I) is quite different from that of the monohydrate. In (I), the torsion angle of $\mathrm{C} 2-\mathrm{C} 1-\mathrm{C} 3-\mathrm{C} 4$ is $170.64(14)^{\circ}$, while, in the monohydrate, the corresponding angle is $-53.08^{\circ}$. As mentioned, there are significant differences between the crystal structures and the side-chain conformations of anhydrous and monohydrate asparagines, which can be attributed most likely to the different hydrogen bonding environment induced by the presence of the water molecules. Similar differences are also found in the crystal structures of $L$-aspartic acid (Derissen et al., 1968) and $L$-aspartic acid monohydrate (Umadevi et al., 2003). The corresponding torsion angles of the side-chains, for example, are $178.2^{\circ}$ and $52.8^{\circ}$, for $L$-aspartic acid and its monohydrate, respectively.

## supplementary materials

## Experimental

The title compound, asparagine oxygen-17 isotope enriched at the carboxyl group, was synthesized with the aim to perform solid-state ${ }^{17} \mathrm{O}$ NMR experiments. L-Asparagine was obtained by deprotection of both the N -terminus and side-chain groups from ${ }^{17} \mathrm{O}$-enriched N - $\alpha$-Fmoc-N- $\beta$-trityl- $L$-asparagine. Detailed procedures have been described elsewhere (Yamada et al., 2007).

Colorless crystals of $L$-asparagine monohydrate can be obtained by slow cooling of an aqueous solution (Verbist et al., 1972; Ramanadham et al., 1972). Colorless platelike crystals of anhydrous $L$-asparagine used in the present study, on the other hand, were obtained from a saturated aqueous solution after it was left standing at room temperature for a few months.

## Refinement

All H atoms were found in difference density Fourier maps. Their positions and isotropic displacement parameters were freely refined. The refined $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ bond lengths are in the expected range: 1.00 (3) $\AA$ and $107.6(18)-109.8(15)^{\circ}$ for the methyne $\mathrm{C}-\mathrm{H}$ distance and the $\mathrm{C} / \mathrm{N}-\mathrm{C}-\mathrm{H}$ angle, respectively; 1.01 (3)-1.03 (3) $\AA, 107.3(15)-110.9(18)^{\circ}$ and $110(2)^{\circ}$ for the methylene $\mathrm{C}-\mathrm{H}, \mathrm{C}-\mathrm{C}-\mathrm{H}$ and $\mathrm{H}-\mathrm{C}-\mathrm{H}$ values, respectively; 0.92 (4)-1.01 (3) $\AA, 109(2)-114.5(18)^{\circ}$ and $105(2)-112(3)^{\circ}$ for the ammonium $\mathrm{N}-\mathrm{H}, \mathrm{C}-\mathrm{N}-\mathrm{H}$ and $\mathrm{H}-\mathrm{N}-\mathrm{H}$ values, respectively; 0.92 (3)-0.94 (3) $\AA$, $118.6(15)-120.2(16)^{\circ}$ and $121(2)^{\circ}$ for the amide $\mathrm{N}-\mathrm{H}, \mathrm{C}-\mathrm{N}-\mathrm{H}$ and $\mathrm{H}-\mathrm{N}-\mathrm{H}$ values, respectively. The range of the $U_{\text {iso }}$ values for the H atoms is $0.020(7)-0.044(9) \AA^{2}$.

## Special details

Experimental. All Friedel pairs were merged, and all f"s of containing atoms were set to zero.

## supplementary materials

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.

Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit S are based on $\mathrm{F}^{2}$, conventional $R$-factors $R$ are based on F , with F set to zero for negative $\mathrm{F}^{2}$. The threshold expression of $\mathrm{F}^{2}>2 \sigma\left(\mathrm{~F}^{2}\right)$ is used only for calculating $R$ factors (gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.
