

Tetra- μ_3 -tert-butoxo-tetrakis[ethyl-zinc(II)]

Stephen C. Moratti and Jim Simpson*

Department of Chemistry, University of Otago, PO Box 56, Dunedin, New Zealand
Correspondence e-mail: jsimpson@alkali.otago.ac.nz

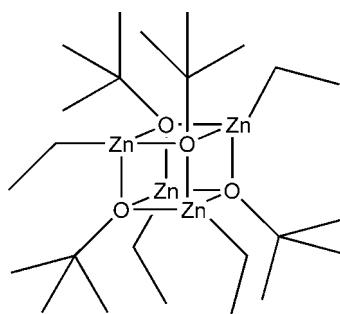

Received 21 August 2007; accepted 27 August 2007

Key indicators: single-crystal X-ray study; $T = 220\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.013\text{ \AA}$; disorder in main residue; R factor = 0.061; wR factor = 0.169; data-to-parameter ratio = 19.2.

In the structure of the title compound, $[\text{Zn}_4(\text{C}_2\text{H}_5)_4(\text{C}_4\text{H}_9\text{O})_4]$, the Zn and O atoms form a distorted cubic arrangement with each Zn atom carrying an ethyl substituent. A *tert*-butyl group is bound to each of the O atoms. Coordination about the Zn and O atoms is distorted tetrahedral. Three of the four ethyl substituents are disordered over two positions; the site occupancy factors are *ca* 0.56 and 0.44. There are no significant close contacts in the crystal structure.

Tetra- μ_3 -tert-butoxo-tetrakis[ethylzinc(II)]

S. C. Moratti and J. Simpson

Comment

Zinc oxide films show promise in a wide variety of optoelectronic devices such as photovoltaics (Delahoy & Cherny, 1996) and sensors (Dimova-Malinovska 2005) due to their electrical conductivity and transparency. While purely inorganic sol-gel, electrochemical or CVD techniques are often employed to make zinc oxide films, another technique is to use organozinc compounds that hydrolyse before or after film deposition. For instance, composite films of zinc oxide have been produced by the spincoating and subsequent hydrolysis of THF solutions of diethyl zinc (Beek *et al.*, 2005). The THF solvent was apparently able to stabilize the otherwise reactive organozinc in order to form good films. In an attempt to use t-butanol as a solvent for zinc oxide thin film deposition with diethyl zinc, we found that large needles of the partially alcoholized zinc title compound, (I), crystallized out after a few minutes.

In the structure of (I) (Fig 1) each Zn atom carries an ethyl substituent and binds to three t-butoxo O atoms. The resulting tetrameric unit is a distorted cube with the Zn and O atoms in distorted tetrahedral arrangements and Zn—O distances in the range 2.084 (4) Å to 2.055 (4) Å [mean 2.073 (6) Å]. This compares with a mean value of 2.07 (2) Å for the 11 other cubic tetrakis(μ_3 -alkyloxo)tetra-alkyl-tetrazinc complexes reported previously (Bond *et al.*, 2001; Herman *et al.*, 1992; Polarz *et al.*, 2005 and Shearer & Spencer, 1980; Boyle *et al.*, 2004). In the crystal structure of (I) there are no significant close contacts with the shortest intermolecular C62···H32Dⁱ ($i = x, y - 1, z$) distance being 3.02 Å.

Experimental

A solution of diethyl zinc in toluene (1 ml, 15 wt%) was added to dry t-butanol (10 ml) at 303 K. After several minutes, colourless needles of (I) started to form, and the reaction appeared complete after 30 minutes. The crystal was mounted for X-ray data collection immersed in the reaction solvent.

Refinement

The atoms of the ethyl groups bound to three of the four Zn atoms are disordered over two positions. The C atoms of these disordered groups were refined with common isotropic displacement parameters. The occupancy factor of the major disorder component refined to 0.559 (9). All H-atoms were positioned geometrically and refined using a riding model with C—H = 0.98 Å and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ for CH₂ groups and C—H = 0.97 Å, $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ for CH₃ groups.

methods

Special details

Experimental. Three of the four ethyl groups are disordered, each over two sites. Common, isotropic displacement parameters were applied to the carbon atoms in all four of these groups.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
