Received 17 October 2007; accepted 29 October 2007

Key indicators: single-crystal X-ray study;  $T = 100$  K; mean  $\sigma(\text{C}-\text{C}) = 0.005$  Å;  $R$  factor = 0.045;  $wR$  factor = 0.111; data-to-parameter ratio = 24.0.

The crystal structure of the low-temperature phase of diethylammonium tetrachloridocuprate(II),  $(\text{C}_4\text{H}_{12}\text{N})_2[\text{CuCl}_4]$ , has been determined by Simonsen & Harlow [(1977). *Am. Crystallogr. Assoc. Ser. 2* Vol. 5, No. 1, Abstract HN5], but no atomic coordinates are available. We therefore redetermined the structure at 100 K. It comprises three crystallographically independent formula units linked by hydrogen bonds into a two-dimensional network. One tetrachloridocuprate(II) anion is virtually square-planar while the two others are tetrahedrally distorted.

### Related literature

The compound was prepared according to Van Oort (1988). For a previous structure report of the low-temperature polymorph of diethylammonium tetrachloridocuprate(II), see: Simonsen & Harlow (1977). The high-temperature polymorph [phase transition at 323 (1) K] was determined by Bloomquist *et al.* (1988), and high- and low-temperature forms of the dipropylammonium analogue were reported by Bond *et al.* (1988).

## The low-temperature phase of diethylammonium tetrachloridocuprate(II)

C. E. Strasser, S. Cronje and H. G. Raubenheimer

### Comment

In the course of an experiment in the inorganic chemistry practical at our university the thermochromic behaviour of diethylammonium tetrachloridocuprate(II) (I) is studied. Surprisingly, atomic coordinates of the low-temperature phase have only been presented at a meeting of the American Crystallographic Association (Simonsen & Harlow, 1977), but not published in a journal or deposited in a data base. However, the structure is briefly discussed in a later publication together with the high-temperature phase (Bloomquist *et al.*, 1988). Redetermination of the crystal and molecular structure was now done at 100 K from a crystal obtained at 293 K.

The molecular and crystal structures of both high- and low-temperature phases of other dialkylammonium tetrachlorocuprates(II), the anion being approximately tetrahedral and square-planar, respectively, have been determined, for example the dipropylammonium analogue (Bond *et al.*, 1988).

The asymmetric unit of (I) is shown in Figure 1. The compound consists of three crystallographically independent formula units of which the anion containing Cu2 is virtually square-planar, the others show a certain degree of distortion towards tetrahedral. The r.m.s. deviations of the atoms constituting the anions from a plane fitted to them is 0.588, 0.017 and 0.344 Å for Cu1, Cu2 and Cu3, respectively. Except for N2 which only engages in one hydrogen bond to Cl12, the other five diethylammonium cations each link two tetrachlorocuprate anions to form a two-dimensional hydrogen-bond network in the (101) plane. Likewise, all chlorine atoms of the anions are hydrogen bond acceptors with the exception of Cl34 (see Table). The connectivity of the hydrogen bonds is shown in Figure 2, a perspective view in Figure 3. Bond lengths and angles are unexceptional.

### Experimental

The compound was prepared according to literature (Van Oort, 1988) and crystallized at room temperature by diffusing diethyl ether vapour into an ethanolic solution. A suitable emerald green crystal was quickly covered in oil and transferred to the cold nitrogen stream of the diffractometer.

### Refinement

All H atoms were positioned geometrically (C—H = 0.98 and 0.99 Å for CH<sub>3</sub> and CH<sub>2</sub>, respectively; and N—H = 0.92 Å) and constrained to ride on their parent atoms;  $U_{iso}(H)$  values were set at 1.2 times  $U_{eq}(C,N)$  for CH<sub>2</sub> or NH<sub>2</sub> and 1.5 times  $U_{eq}(C)$  for CH<sub>3</sub>.

Figures

Fig. 1. Asymmetric unit of (I). Ellipsoids are shown at the 50% probability level, hydrogen bonds are shown with dashed lines. C—H hydrogen atoms are omitted for clarity.

Fig. 2. Schematic representation of the hydrogen bonding network. Hydrogen bonds are shown as dashed lines and bonds to symmetry equivalent atoms as wiggled lines. Symmetry operators: (i)  $x, y + 1, z$ ; (ii)  $-x + 1, -y + 1, -z$ ; (iii)  $-x + 1/2, y + 1/2, -z + 1/2$ ; (iv)  $-x + 1/2, y - 1/2, -z + 1/2$ ; (v)  $x, y - 1, z$ .

Fig. 3. Perspective view of the hydrogen-bonded layer. Atoms are drawn as spheres of arbitrary radius, only N—H hydrogen atoms are shown. Symmetry operators: (iii)  $-x + 1/2, y + 1/2, -z + 1/2$ ; (iv)  $-x + 1/2, y - 1/2, -z + 1/2$ ; (vi)  $x - 1/2, -y + 1/2, z + 1/2$ ; (vii)  $x - 1/2, -y + 3/2, z + 1/2$ ; (viii)  $-x, -y + 1, -z + 1$ .

Primary atom site location: structure-invariant direct methods	$\Delta\rho_{\min} = -0.49 \text{ e } \text{\AA}^{-3}$
	Extinction correction: none

Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2\sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
