Received 29 October 2007; accepted 7 November 2007

Key indicators: single-crystal X-ray study; $T = 297$ K; mean $\sigma(\text{C}-\text{C}) = 0.006$ Å; R factor = 0.031; wR factor = 0.083; data-to-parameter ratio = 10.1.

The polymeric structure of the title compound, poly[[diaquabis(μ -biphenyl-4,4'-disulfonato)tetrapotassium(I)] dihydrate], $\{[\text{K}_2(\text{C}_{12}\text{H}_8\text{O}_6\text{S}_2)(\text{H}_2\text{O})]\cdot\text{H}_2\text{O}\}_n$, is based on an asymmetric unit comprising three independent and different potassium centres, one six-coordinate [$\text{K}-\text{O} = 2.657$ (3)– 2.866 (5) Å], one seven-coordinate [$\text{K}-\text{O} = 2.703$ (3)– 3.040 (4) Å], and the third ten-coordinate [$\text{K}-\text{O} = 2.751$ (3)– 3.079 (4) Å], with two of these lying on crystallographic mirror planes. The four half-occupancy water molecules also lie on the mirror planes with two coordinated (one monodentate, the other bidentate bridging) and two as molecules of solvation. The interlinked coordination polyhedra form chains which are joined laterally through the biphenyl residues as well as through head-to-tail water hydrogen-bonding interactions, giving a two-dimensional structure.

Dipotassium biphenyl-4,4'-disulfonate dihydrate: a coordination polymer

G. Smith, U. D. Wermuth and P. C. Healy

Comment

Compounds of 4,4'-biphenyldisulfonic acid (BPDS) are not numerous in the crystallographic literature. The guanidinium salts have been used for the generation of 2-D structures for the formation of crystalline clathrates with aromatic hydrocarbons (Swift *et al.*, 1998; Pivovar *et al.*, 2002). The bis(alaninium) salt is also known (Liao *et al.*, 2001). With coordination compounds, BDPDS is generally found as a dianionic counter ion (Cai *et al.*, 2001; Usuki *et al.*, 2002). We obtained X-ray diffraction quality crystals of the hydrated dipotassium salt of BPDS as an intermediate in the synthesis of BPDS, when recrystallized from water. The structure of this compound, $K_2^{2+} \cdot C_{12}H_8O_6S_2^{2-} \cdot 2H_2O$ (I) is reported here.

The structure of (I) is based on an asymmetric unit comprising three independent and different potassium centres, one six-coordinate (K2) [K–O range, 2.657 (3)–2.866 (5) Å], one seven-coordinate (K1) [K–O range, 2.703 (3)–3.040 (4) Å] and the third ten-coordinate (K3) [K–O range, 2.751 (3)–3.079 (4) Å], with two of these (K2 and K3) lying on crystallographic mirror planes (Fig. 1). The four half-occupancy water molecules also lie on the mirror planes with two coordinated [one monodentate (O1W on K2), and one bidentate (O2W, bridging K2 and K3)], and the other two (OW3, OW4) as molecules of solvation. The structure has pseudo $2/m$ symmetry, the 2-fold rotational symmetry along the b axis being upset largely by the differing roles of the water molecules in the structure. This was also consistent with the failure to obtain a solution of the structure in the space group $C2/m$.

The interlinked potassium coordination polyhedra form chains which extend down the b axis and are linked laterally across the c cell direction through the biphenyl residues of the BPDS ligands, giving a 2-D structure (Fig. 2). This is somewhat analogous to the 2-D but hydrogen-bonded guanidinium-BPDS open framework structures (Swift *et al.*, 1998; Pivovar *et al.*, 2002) which accommodate interstitial inert aromatic molecules. With (I), the water molecules are similarly accommodated in the interstitial spaces along the crystallographic mirror planes in linear head-to-tail interactions (Table 1) and also link the coordination polymer chains. In addition, the coordinated water molecules give lateral $O-H \cdots O_{\text{sulfonate}}$ interactions within the polymer chains.

Within the BPDS anion, the two phenyl rings (A and B) are close to co-planar [torsion angle C2A–C1A–C1B–C6B, -178.3 (5) °], which is similar to that found in the alaninium salt where the two residues are inversion related (Liao *et al.*, 2001).

Experimental

The title compound was obtained as colourless crystals from the room temperature evaporation of an aqueous solution of dipotassium 4,4-biphenyldisulfonate, an intermediate product in the synthesis of 4,4'-biphenyldisulfonic acid by the sulfonation of biphenyl using the procedure of Feldmann (1931).

Refinement

Hydrogen atoms on the water molecules were located by difference methods but their positional and isotropic displacement parameters were fixed as located and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{O})$, respectively; see Table 1 for distances. The aromatic H atoms were included in the refinement in their calculated positions (C–H = 0.94–0.95 Å) using a riding model approximation, with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$.

Figures

Fig. 1. Molecular configuration and atom naming scheme for the BPDS ligand, the three independent potassium coordination polyhedra and the water molecules in the asymmetric unit of (I). Displacement ellipsoids are drawn at the 50% probability level. Dashed lines indicate hydrogen-bonding interactions associated with the water molecules. The two potassium ions (K2, K3) and the four water molecules (O1W–O4W) lie on a crystallographic mirror plane. Symmetry codes: (i) $x - 1, y, z$; (ii) $x - 1, y, z + 1$; (iii) $x, y, z + 1$; (iv) $x - 1/2, -y + 1/2, z$; (v) $x - 1/2, -y + 1/2, z + 1$; (vi) $x - 1, -y, z + 1$; (vii) $x, -y, z + 1$; (viii) $x + 1, y, z$; (ix) $x, -y, z$.

Fig. 2. The 2-D hydrogen-bonded structure of (I) viewed down the a axis, showing $K\text{-O}_{\text{sulfonate}}$ coordination-polymer chains with the biphenyl step linkages, together with the water mediated hydrogen-bonding associations lying on the mirror planes at $y = 0, 1/2$.

Special details

Geometry. Bond distances, angles *etc.* have been calculated using the rounded fractional coordinates. All su's are estimated from the variances of the (full) variance-covariance matrix. The cell e.s.d.'s are taken into account in the estimation of distances, angles and torsion angles

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
