Received 23 February 2008; accepted 6 March 2008

Key indicators: single-crystal X-ray study; $T = 296$ K; mean $\sigma(\text{C}-\text{C}) = 0.006$ Å; H-atom completeness 98%; disorder in solvent or counterion; R factor = 0.051; wR factor = 0.137; data-to-parameter ratio = 15.6.

In the title compound, $[\text{Cu}(\text{C}_{10}\text{H}_8\text{N}_2)(\text{C}_{18}\text{H}_{15}\text{P})_2]\text{NO}_3 \cdot \text{CHCl}_3 \cdot 0.5\text{H}_2\text{O}$, the Cu atom is tetrahedrally coordinated by a bidentate 2,2'-bipyridine ligand and two PPh_3 ligands. The Cu–N and Cu–P distances are similar to those observed in similar compounds. The range of coordination angles shows a moderate distortion from ideal tetrahedral geometry. The bipyridine ligand is twisted $[14.2(4)^\circ]$ about the ring–ring C–C bond. The nitrate anion and the water and chloroform molecules of solvation are disordered. In the crystal structure, there are O(water)–H \cdots O(nitrate), C–H \cdots O(water) and C–H \cdots O(nitrate) hydrogen bonds.

(2,2'-Bipyridine)bis(triphenylphosphine)copper(I) nitrate chloroform solvate hemihydrate

M. Navarro, O. A. Corona, T. González and M. V. Capparelli

Comment

The title compound (I) was prepared within our program of studies of copper complexes containing N-bidentated aromatic ligands, focused on the search for drugs with biological activity, especially against parasitic diseases (Navarro *et al.*, 2003).

The structure analysis showed that, in addition to the complex cation and the (partially disordered) nitrate anion the crystals contain disordered molecules of water and chloroform of solvation.

In the cation (Fig. 1), the metal atom is tetrahedrally coordinated to a bidentated 2,2'-bipyridine (bipy) ligand and to two PPh₃ moieties. The Cu—N and Cu—P (Table 1) distances are comparable to Cu—N, 2.056 (8), 2.113 (9) Å and Cu—P, 2.246 (3), 2.256 (3) Å observed in the same cation in [Cu(PPh₃)₂(bipy)]ClO₄ (Engelhardt *et al.*, 1985). All bond lengths and angles in the organic ligands are within normal values (Allen *et al.*, 1987).

The range of coordination angles (Table 1) shows a moderate distortion from the ideal tetrahedral geometry. As expected, the bite angle is the smaller one, while the P—Cu—P angle is the largest, due to the bulkiness of the PPh₃ moieties. The five-member metallacycle, Cu1—N1—C6—C7—N2, can be described as an envelope on C6, albeit a flat one [C6 is 0.148 (4) Å out of the plane]. The bipy ligand is twisted about C6—C7 (Table 1); the dihedral angle between both heterocycles is 17.0 (2)°.

Although the water's H atoms could not be located (see Refinement Section), short contacts with the nitrate anion [O1w...O2s(1 + x, y, z), 2.663 (19) Å; O1w...O2s(1 - x, 2 - y, -z), 2.667 (19) Å] indicate hydrogen bonds between these two groups. Further evidence of the feasibility of these links is given by the corresponding O2s...O1w...O2s angle [146.7 (5)°]. Several C—H...O bonds may also contribute to the crystal packing (Fig. 2 and Supplementary material).

Experimental

The title compound (I) was synthesized by the reaction of copper nitrate with bipyridine. To a solution of Cu(PPh₃)₂NO₃ (100 mg, 0.15 mmol) in dichloromethane (10 ml) was added 2,2'-bipyridine (24 mg, 0.15 mmol). The solution, initially transparent, became yellow. It was stirred for 1 h at room temperature and then was added to hexane (50 ml). The light yellow solid formed was filtered and dried (122 mg, 98%). All operations were carried out under inert atmosphere. Crystals suitable for X-ray analysis were obtained by slow evaporation of a chloroform solution.

Refinement

The hydrogen atoms were placed in calculated positions using a riding atom model with fixed C—H distances [0.93 Å for C(sp²), 0.98 Å for C(sp³) in CHCl₃] and $U_{\text{iso}} = 1.2 U_{\text{eq}}(\text{parent atom})$.

supplementary materials

The nitrate anion and the water and chloroform molecules of solvation were found to be disordered. The NO_3^- showed severe disorder, difficult to model satisfactorily; in the final refinement the four largest residual electron density peaks were close ($0.64\text{--}1.07\text{ e}/\text{\AA}^3$) to NO_3 atoms. O2s and O3s were split in two positions, with complementary occupancies, and refined isotropically to final occupancies of 0.505 (14) and 0.719 (12) respectively. To obtain better geometries, restraints were applied: SADI to all N—O bonds and to all O \cdots O distances, and FLAT to both NO_3 groups. An attempt at splitting N1s, as suggested by its elongated ADP, gave meaningless results. The O1w atom of the water molecule was given an occupancy of 1/2, since it is disordered between two centrosymmetrically related positions, which are mutually exclusive [O1w \cdots O1w(2 - x, 2 - y, -x), 1.53 (3) \AA]. The corresponding H atoms could not be found. Each of the Cl atoms of chloroform was split in two alternative positions, with complementary occupancies. The main positions [final occupancy 0.911 (6) for all three] were refined anisotropically, while the alternative ones were given isotropic displacement parameters.

Both Cu—P bonds, with $\Delta U/\sigma = 7.21$ for Cu1—P1 and 7.13 for Cu1—P2, failed to pass the standard rigid-bond test (e.g.: $\Delta U/\sigma \leq 5$, Spek, 1998; Hirshfeld, 1976) even after applying a DELU restraint (Sheldrick, 2008). This was probably due to an unfavorable specimen morphology which caused a poor absorption correction.

Figures

Fig. 1. Structure of the complex cation $[\text{Cu}(\text{PPh}_3)_2(\text{bipy})]^+$ showing the atomic numbering. Displacement parameters are drawn at 50% probability level.

Fig. 2. Crystal structure of (I). For clarity, alternative positions for disordered atoms and H atoms were omitted. Possible hydrogen bonds are shown as dashed lines.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger. Refinement details for disordered atoms are given in the Refinement section.
