Correspondence e-mail: g.portalone@caspur.it

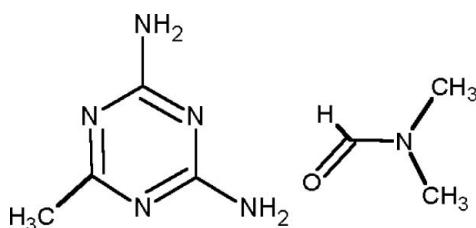

Received 18 July 2008; accepted 28 July 2008

Key indicators: single-crystal X-ray study;  $T = 298$  K; mean  $\sigma(C-C) = 0.005$  Å;  
 $R$  factor = 0.047;  $wR$  factor = 0.127; data-to-parameter ratio = 8.5.

The structure of acetoguanamine (or 2,4-diamino-6-methyl-1,3,5-triazine) has been determined as the *N,N*-dimethyl-formamide solvate,  $C_4H_7N_5 \cdot C_3H_7NO$ . The molecular components are associated in the crystal structure to form ribbons stabilized by three N–H···N and one N–H···O hydrogen bonds which involve NH groups as donors and the N atoms of the heterocyclic ring and the carbonyl O atom of the solvent as acceptors.

## Acetoguanamine *N,N*-dimethylformamide solvate

### G. Portalone

#### Comment

As a part of a more general study of multiple-hydrogen-bonding DNA/RNA nucleobases as potential supramolecular reagents (Portalone *et al.*, 1999; Portalone & Colapietro, 2007a, b), this work is a continuation of our studies on crystal adducts of DNA/RNA pyrimidine bases coupled with amino-derivatives of aromatic *N*-heterocycles *via* multiple hydrogen bonds to mimic the base-pairing of nucleic acids.

The asymmetric unit of (I) comprises a planar independent molecule of acetoguanamine hydrogen-bonded to *N,N*-dimethylformamide (DMF) (Fig. 1). A comparison of the molecular geometry of acetoguanamine with that reported for the corresponding molecule in the 1:1 monohydrated molecular adduct formed between acetoguanaminium chloride and acetoguanamine (Portalone & Colapietro, 2007a) shows that the corresponding bond lengths and angles are equal within experimental error. An analysis of the crystal packing of (I) shows (Table 1) that adjacent molecules of acetoguanamine are linked into ribbons (Fig. 2) by three independent intermolecular N—H···N hydrogen bonds between NH moieties and N atoms of the heterocyclic ring to form hydrogen-bonded rings (one centrosymmetric) of descriptor  $R^2_{2}(8)$  (Etter *et al.*, 1990; Bernstein *et al.*, 1995; Motherwell *et al.*, 1999). These hydrogen bonds that lead to two-dimensional arrays in the *ab* plane are bridged by DMF molecules *via* N—H···O interactions forming  $C^1_1(3)$  chains.

#### Experimental

Acetoguanamine (0.1 mmol, Sigma Aldrich at 98% purity) was dissolved in *N,N*-dimethylformamide (9 ml) and heated under reflux for 3 h. After cooling the solution to an ambient temperature, crystals suitable for single-crystal X-ray diffraction were grown by slow evaporation of the solvent after a few days.

#### Refinement

All H atoms were found in a difference map, positioned with idealized geometry, and refined isotropically using a riding model (N—H = 0.82–0.89 Å, C—H = 0.93–0.97 Å). Their  $U_{\text{iso}}$  values were kept equal to  $1.2U_{\text{eq}}(\text{N})$ ,  $1.5U_{\text{eq}}(\text{C})$ ,  $2.0U_{\text{eq}}(\text{C})$  of the solvent molecule. In the absence of significant anomalous scattering, Friedel pairs were merged.

#### Figures

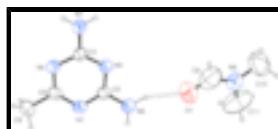

Fig. 1. The molecular structure of (I), showing the atom-labelling scheme. Displacements ellipsoids are at the 50% probability level.

## supplementary materials

---

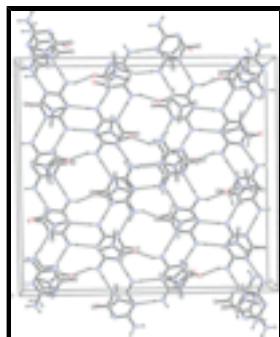

Fig. 2. Crystal packing diagram for (I) viewed approximately down the *c*-axis. All atoms are shown as small spheres of arbitrary radii. For the sake of clarity, only H atoms involved in hydrogen bonding are shown. Hydrogen bonding is indicated by dashed lines.

#### Refinement

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: inferred from neighbouring sites
$R[F^2 > 2\sigma(F^2)] = 0.047$	H-atom parameters constrained
$wR(F^2) = 0.127$	$w = 1/[\sigma^2(F_{\text{o}}^2) + (0.0841P)^2]$
	where $P = (F_{\text{o}}^2 + 2F_{\text{c}}^2)/3$

$S = 0.91$	$(\Delta/\sigma)_{\max} < 0.001$
1127 reflections	$\Delta\rho_{\max} = 0.15 \text{ e \AA}^{-3}$
132 parameters	$\Delta\rho_{\min} = -0.14 \text{ e \AA}^{-3}$
1 restraint	Extinction correction: none
Primary atom site location: structure-invariant direct methods	

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
