BaCo₂Sn₄O₁₁**Hisanori Yamane,^{a*} Takeshi Ono^b and Takahiro Yamada^a^aInstitute of Multidisciplinary Research for Advanced Materials, Tohoku University, 2-1-1 Katahira, Aobaku, Sendai 980-8577, Japan, and ^bCenter for Interdisciplinary Research, Tohoku University, Aramaki Aza-Aoba, Aobaku, Sendai 980-8578, Japan
Correspondence e-mail: yamane@tagen.tohoku.ac.jp

Received 10 September 2008; accepted 23 September 2008

Key indicators: single-crystal X-ray study; $T = 293$ K; mean $\sigma(\text{Co}-\text{O}) = 0.004$ Å; disorder in main residue; R factor = 0.018; wR factor = 0.041; data-to-parameter ratio = 8.2.

BaCo₂Sn₄O₁₁ is isotypic with *R*-ferrite, BaTi₂Fe₄O₁₁. The Co atoms fully occupy trigonal-bipyramidal sites ($\bar{6}m2$) and are disordered with Sn atoms in octahedral sites ($.2/m$ symmetry), as represented in the formula BaCoSn₂(Co_{0.34}Sn_{0.66})₄O₁₁. Ba atoms are situated in a 12-fold coordinated site ($\bar{6}m2$ symmetry).

R-Ferrite-type barium cobalt stannate, BaCo₂Sn₄O₁₁

H. Yamane, T. Ono and T. Yamada

Comment

BaTi₂Fe₄O₁₁ crystallizes in a six-layer hexagonal structure (*R*-type, space group *P*6₃/*mmc*) (Haberey & Velicescu, 1974; Obradors *et al.*, 1983; Cadée & Ijdo, 1984; Sosnowska *et al.*, 1996) that is adopted by many multinary iron oxides and transition metal oxides exhibiting complex magnetic behavior (Cadée & Ijdo, 1984; Kanke *et al.*, 1992; Martínez *et al.*, 1993; Foo *et al.*, 2006). BaCo₂Sn₄O₁₁ has been indicated to be the end member in a solid solution series BaFe_{4-2x}Sn_{2+x}Co_xO₁₁, where the distribution of Fe, Co, and Sn cations was determined by combined powder X-ray and neutron diffraction (Martínez *et al.*, 1993). However, no crystallographic information (cell parameters and atomic positions) was reported except for the Co and Sn site occupancies in BaCo₂Sn₄O₁₁. The present paper reports the detailed structure of BaCo₂Sn₄O₁₁ determined by single-crystal X-ray diffraction.

The structure of BaCo₂Sn₄O₁₁ can be described in terms of cation-centered oxygen polyhedra (Fig. 1). The disorder within the octahedral 6g site (occupancies of 0.664 (7) Sn1 and 0.336 (7) Co1) agrees with results reported by Martínez *et al.* (1993) (0.7 Sn1 and 0.3 Co1). These Sn1/Co1-centered octahedra share edges to form layers perpendicular to the *c* axis. Located between these layers are pillars of two face-sharing Sn2-centered octahedra stacked along the *c* axis. The trigonal bipyramidal 2d site is occupied exclusively by Co2 atoms and exhibits a displacement ellipsoid elongated along the *c* direction (Fig. 2). Ba atoms are situated in a 12-fold coordination site (2c).

Experimental

A mixture of BaCO₃ (99.99%, Wako Pure Chemical Ind.), Co₃O₄ (99.95%, Kanto Chemical Co. Inc.), and SnO₂ (99.9%, Rare Metallic Co. Ltd.) powders in a molar ratio of Ba:Co:Sn = 1:2:4 was ground together and pressed into a pellet. The pellet was placed on a platinum plate and heated in air for 1 h at 1473 K or 1823 K in an electric furnace. The pellet was melted at 1823 K and green transparent single crystals of BaCo₂Sn₄O₁₁ were obtained. The chemical analysis of the polycrystalline single phase BaCo₂Sn₄O₁₁ prepared at 1473 K was carried out by inductively coupled plasma (ICP) emission spectrometry for Ba, Co and Sn, and by the He carrier melting-infrared absorption method (TC-436, LECO) for O. The results of the chemical analysis (Ba 14.9 (5), Co 13.8 (5), Sn 52.9 (8), and O 19.1 (8) wt%) agreed with the ideal contents (Ba 15.2, Co 13.4, Sn 51.9, O 19.5 wt%).

The magnetic susceptibility of BaCo₂Sn₄O₁₁ was measured with a superconducting quantum interference device (SQUID) magnetometer (Quantum Design, MPMS XL) from 5 to 400 K under a magnetic field of 5 kOe. The polycrystalline sample followed the Curie–Weiss law above the Neel temperature (*T*_N). The *T*_N of 7 K, the Weiss temperature (Θ) of -42 K, and the magnetic moment (μ_{eff}) of 4.7 μ_{B} per Co measured for the sample were consistent with the values reported by Martínez *et al.* (1993) (*T*_N = 9 K, Θ = -44 K, μ_{eff} = 4.4 μ_{B}).

Refinement

In the structure analysis using powder X-ray and neutron diffraction data for BaTi₂Fe₄O₁₁ and BaSn₂Fe₄O₁₁ (Obradors *et al.*, 1983; Cadée & Ijdo, 1984; Martínez *et al.*, 1993), the 2*d* site of Fe atoms was statistically split into two site (4*f*). We applied this split site model and refined the positional parameter of *z* for the Co₂ site, but it converged into 0.250 within an estimated deviation. Thus, we fixed the position at 2*d* site for the final refinement.

Figures

Fig. 1. Structure of BaCo₂Sn₄O₁₁ in terms of cation-centered oxygen polyhedra.

Fig. 2. The O-atom coordination around the cation sites of BaCo₂Sn₄O₁₁ (symmetry codes as in Table 1). Displacement ellipsoids are drawn at the 99% probability level.

Refinement

Refinement on F^2	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.018$	$w = 1/[\sigma^2(F_o^2) + 0.8941P]$
$wR(F^2) = 0.041$	where $P = (F_o^2 + 2F_c^2)/3$
$S = 1.13$	$(\Delta/\sigma)_{\text{max}} < 0.001$
230 reflections	$\Delta\rho_{\text{max}} = 0.73 \text{ e } \text{\AA}^{-3}$
28 parameters	$\Delta\rho_{\text{min}} = -1.81 \text{ e } \text{\AA}^{-3}$
1 restraint	Extinction correction: SHELXL97 (Sheldrick, 2008), $F_c^* = kFc[1+0.001xFc^2\lambda^3/\sin(2\theta)]^{-1/4}$
	Extinction coefficient: 0.0041 (4)

Special details

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
