Key indicators: single-crystal X-ray study; $T=109 \mathrm{~K}$; mean $\sigma(\mathrm{B}-\mathrm{Rh})=0.00007 \AA$; disorder in main residue; $R$ factor $=0.014 ; w R$ factor $=0.029$; data-to-parameter ratio $=17.5$.

In contrast with previous structural studies of ytterbium trirhodium boride, $\mathrm{YbRh}_{3} \mathrm{~B}$, that suggest a boron deficiency, the current redetermination of the crystal structure of $\mathrm{YbRh}_{3} \mathrm{~B}$ revealed instead a rhodium deficiency with a refined composition of $\mathrm{YbRh}_{2.67 \text { (2) }} \mathrm{B}$. In the $A B X_{3}$ perovskite-type structure, $\mathrm{Yb}, \mathrm{B}$ and Rh are located on the $A, B$ and $X$ positions, respectively, with site symmetries of $m \overline{3} m$ for the $A$ and $B$ sites, and $4 / m m . m$ for the $X$ site.

# Redetermination of the perovskite-type compound $\mathbf{Y R h}_{3} \mathbf{B}$ revealing a $\mathbf{R h}$ deficiency 

R. Makita, K. Tanizawa, K. Tanaka and H. Takei

## Comment

Takei \& Shishido (1984) reported various rare earth trirhodium borides with the perovskite structure (Fig. 1) and suggest a deficiency for the boron site. For a closer inspection of this assumption and since anisotropic displacement factors were not reported in the original study, we decided to re-determine the structure of $\mathrm{YbRh}_{3} \mathrm{~B}$ and present the results of the structure analysis in this communication.

In the $A B X_{3}$ perovskite-type structure, $\mathrm{Yb}, \mathrm{B}$ and the partly occupied Rh atoms are located on the $A, B$ and $X$ positions, respectively, with site symmetries of $m \overline{3} m$ for the $A$ and $B$ sites and $4 / m m . m$ for the $X$ site.

## Experimental

Single crystals were grown using a flux method with copper as the solvent. Stoichiometric quantities of $\mathrm{Yb}, \mathrm{Rh}$ and B were mixed with copper in a ratio of about $1: 8$ by weight. The mixture was heated in a high purity alumina crucible by electric furnace under a purified He gas flow at a rate of about $400 \mathrm{Kh}^{-1}$. The sample was kept at a temperature between 1523 and 1623 K for 10 h and cooled at a rate of $1 \mathrm{Kh}^{-1}$ to 353 K . Then the furnace was cooled rapidly to room temperature. The boride crystals were separated from the copper by treatment with hot nitric acid. The sample was cut into small pieces and was finally ground into a sphere with $41 \mu \mathrm{~m}$ radius by a wind pressure granulation machine with diamond paste.

## Refinement

In the first stage of the refinement the site occupation factors (s.o.f.) of $\mathrm{Yb}, \mathrm{Rh}$ and B were assumed to be 1. Fig. 2 (a), (b) and $(c)$ show the difference density map at this stage of the refinement around $\mathrm{Yb}, \mathrm{Rh}$ and B , respectively. The center of the difference density map is the core of atom; the width and depth of the difference density map is $4.13 \AA \times 4.13 \AA$. The ( $\rho_{\max }, \rho_{\min }$ ) values for $\mathrm{Yb}, \mathrm{Rh}$ and B were $(-4.59,8.48),(-4.92,9.06)$ and $(-4.91,8.58) \mathrm{e} \AA^{-3}$, respectively, with the $R$-factor converging at $3.14 \%$. After this stage we checked the results of Takei \& Shishido (1984) for a deficiency of the boron site and refined the s.o.f. of boron. However, the $R$-factor and the difference density map showed no noticeable improvement. Then the s.o.f. of both Yb and Rh were refined independently. Whereas the s.o.f. of Yb remained unchanged, that of Rh changed from 1 to 0.891 (6). Fig. 3 (a), (b) and (c) show the difference density map around $\mathrm{Yb}, \mathrm{Rh}$ and B after the refinement of the s.o.f. of Rh. The positive and negative peaks showed a significant improvement compared with the first refinement with a constrained s.o.f. for Rh . The remaining electron densities ( $\rho_{\max }, \rho_{\min }$ ) around $\mathrm{Yb}, \mathrm{Rh}$ and B were $(-1.89,1.79)$, $(-1.96,1.86)$ and $(-1.98,1.33)$ e $\AA^{-3}$, respectively, and the $R$-factor converged at $1.4 \%$.
