Received 30 August 2008; accepted 9 September 2008

Key indicators: single-crystal X-ray study; $T = 295\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; R factor = 0.045; wR factor = 0.120; data-to-parameter ratio = 15.2.

The title compound, $[\text{C}_8\text{H}_{18}\text{N}]^+ \cdot [\text{B}_5\text{O}_6(\text{OH})_4]^-$, has been synthesized under mild solvothermal conditions in the presence of *N,N*-dimethylcyclohexylamine acting as a template. The structure consists of pentaborate $[\text{B}_5\text{O}_6(\text{OH})_4]^-$ anions connected through O—H \cdots O hydrogen bonds into a three-dimensional framework, with large channels along [100], [010] and [001] directions. The $[\text{C}_8\text{H}_{18}\text{N}]^+$ cations reside in the channels, interacting with the framework through N—H \cdots O hydrogen bonds.

Cyclohexyldimethylammonium tetrahydroxypentaborate

H. Li, G.-M. Wang, S.-Y. Xue and Q. Liang

Comment

Borate materials have been receiving particular attention due to their fascinating structural diversities and potential applications in mineralogy and industry (Burns *et al.*, 1995; Chen *et al.*, 1995; Grice *et al.*, 1999; Touboul *et al.*, 2003). From a structural point of view, the ability of B to adopt both BO₃ and BO₄ coordination modes, coupled with the tendency of such units to polymerize into a wide range of polyanions, has led to a rapidly growing family of borates. Thus far, numerous inorganic borate materials with alkali metals, alkaline earth metals, rare earths and transition metals have been extensively studied. In contrast, the analogous chemistry of organically templated borates is still relatively undeveloped. To the best of our knowledge, only a few examples with polyanions, such as [B₄O₅(OH)₄] (Batsanov *et al.*, 1982), [B₅O₆(OH)₄] (Wang *et al.*, 2004), [B₇O₉(OH)₅] (Liu & Li, 2006; Liu *et al.*, 2006), [B₉O₁₂(OH)₆] (Schubert *et al.*, 2000) and [B₁₄O₂₀(OH)₆] (Liu *et al.*, 2006), have been reported. The aim of our work is to explore the construction of novel microporous aluminoborates templated by organic agents with different shape and size (Wang *et al.*, 2008a,b). Unexpectedly, the title compound, (I), was isolated, a new organically templated pentaborate.

As shown in Fig. 1, the asymmetric unit of (I) contains one [B₅O₆(OH)₄]⁻ anion and one [C₈H₁₈N]⁺ cation. The anionic [B₅O₆(OH)₄]⁻ polyanion is composed of two common B₃O₃ rings, each containing two BO₃ triangles and one BO₄ tetrahedron. The B—O bond distances lie in the range 1.341 (2)–1.388 (2) Å for the BO₃ triangles (B1, B2, B4 and B5) and 1.452 (2)–1.473 (2) Å for the B(3)O₄ tetrahedron, in good agreement with those reported previously for other borate compounds. The O—B—O bond angles lie in the range 115.8 (2)–123.7 (2) ° for the triangles and 108.4 (2)–111.2 (2) ° for the tetrahedron. The anionic [B₅O₆(OH)₄]⁻ groups are connected to each other through intermolecular O—H···O hydrogen bonds, forming a three-dimensional framework with large channels along [100], [010] and [001] directions. The [C₈H₁₈N]⁺ cations reside in these channels, interacting with the framework through N—H···O hydrogen bonds (Fig. 2).

Experimental

A mixture of H₃BO₃ (0.186 g), Al₂O₃ (0.104 g), *N,N*-dimethylcyclohexylamine (0.75 ml), pyridine (4.4 ml) and H₂O (0.50 ml) was sealed in a Teflon-lined steel autoclave, heated at 453 K for 8 days, and then cooled to room temperature. The homogeneous product consisting of large colorless block-shaped crystals was separated from the solution by filtration, washed with distilled water, and then dried in air.

Refinement

All H atoms were positioned geometrically and treated as riding atoms: O—H = 0.82 Å, N—H = 0.91 Å and C—H = 0.96–0.98 Å with $U_{\text{iso}}(\text{H}) = 1.2\text{--}1.5U_{\text{eq}}(\text{parent atoms})$.

Refinement

Refinement on F^2	Hydrogen site location: inferred from neighbouring sites
Least-squares matrix: full	H-atom parameters constrained
$R[F^2 > 2\sigma(F^2)] = 0.044$	$w = 1/[\sigma^2(F_o^2) + (0.0587P)^2 + 0.0744P]$ where $P = (F_o^2 + 2F_c^2)/3$
$wR(F^2) = 0.119$	$(\Delta/\sigma)_{\max} < 0.001$
$S = 1.08$	$\Delta\rho_{\max} = 0.23 \text{ e \AA}^{-3}$
3318 reflections	$\Delta\rho_{\min} = -0.29 \text{ e \AA}^{-3}$
218 parameters	Extinction correction: SHELXL, $F_c^* = kF_c[1 + 0.001x F_c^2 \lambda^3 / \sin(2\theta)]^{1/4}$
Primary atom site location: structure-invariant direct methods	Extinction coefficient: 0.058 (6)
Secondary atom site location: difference Fourier map	

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
