Received 5 August 2008; accepted 15 October 2008

Key indicators: single-crystal X-ray study; T = 293 K; mean σ (C–C) = 0.003 Å; R factor = 0.029; wR factor = 0.096; data-to-parameter ratio = 14.7.

In the title compound, $[Zn(C_5O_5)(C_{12}H_8N_2)_2]$, the Zn atom is in a slightly distorted octahedral environment. The molecule lies across a twofold rotation axis, around which two 1,10phenanthroline ligands are arranged. There are short contacts between the 1,10-phenanthroline groups and the O atoms of the croconate ligand, which probably stabilize the crystal structure *via* weak C-H···O interactions.

Comment

The dianion of croconic acid(4,5-dihydroxycyclopent-4-ene-1,2,3-trione), $(C_5O_5)^{2-}$, is one of the cyclic aromatic oxocarbons $(CO)_n^{2-}$ characterized by extensive delocalization of the π electrons all over the ring (Seitz & Imming, 1992). Previous reports reveal that croconate is a polydent ligand(Chen *et al.*, 2005, Maji *et al.*, 2003, Wang *et al.*, 2002, Sletten *et al.*, 1998). According to the concept of 'molecular self-organization' and 'molecular engineering', transition metal croconates associated with another ligand such as terpyridine (Castro *et al.* 2002), bis((bis(2-pyridylcarbonyl) amido (Maji *et al.*, 2003), 2,2'-bipyridine (Castro *et al.*, 1992) or the tetrakis(2-pyridyl)pyrazine (Carranza *et al.* 2004) show interesting properties in magnetism, biochemistry, catalyst *et al.*

1,10-Phenanthroline(phen) is a well known neutral bidentate ligand. There have been considerable interests in the synthesis of open-framework phen-based metal complexes because of their interesting structure chemistry and potential applications(Faus *et al.* 1994). Recently, many research activities have focused on the synthesis of hybrid framework by incorporate organic ligand in the structure of phen-based complexes. Among the family of cyclic oxocarbons of the formula $(CO)_n^{2-}$ [n=2–6 for oxalate, deltate, squarate, croconate and rhodizonate anions, respectively], the croconate moiety, $(C_5O_5)^{2-}$, was found to be a good candidate and has been successfully incorporated into phen-based frameworks in our previous work, [*M*(phen)₂(C₅O₅)] (*M*= Cu, Ni, Co, Mn) (Chen *et al.*, 2005, 2007, 2008). Here, we report a new member of this family: [Zn(phen)₂(C₅O₅)].

In the title structure, asymmetry unit contains a phen moiety and half a coroconte group coordinated with a zinc ion. The title compound lies across twofold rotation axes which passes through the Zn atom and bisects the croconate ligand, around which two phen ligand are arranged in a chiral propeller manner. A unit cell contains four $[Zn(phen)_2(C_5O_5)]$ molecules.

As a good π -conjugation system, the croconate dianion('free' ligand) in its simple salt has a plannar D_{5 h} conformation with five almost identical C?O bonds and five almost identical C?C bonds, such as in Rb₂C₅O₅ and Cs₂C₅O₅ crystals (Braga *et al.*, 2002). However, the coordinated ligand in title complex obvioulsy deviates from D_{5 h} symmetry. The C?O bond involving coordinated O atoms is longer than that involving the uncoordinated O atoms. In the title complex, the C?O bond lengths are 1.229 (3) Å and 1.228 (4) Å for the uncoordinated O atoms and 1.277 (2) Å for the coordinated O atoms.

The molecuar conformation of $[Zn(phen)_2(C_5O_5)]$ is close to $[Co(phen)_2(C_5O_5)]$ and $[Ni(phen)_2(C_5O_5)]$ while different from $[Cu(phen)_2(C_5O_5)]$ and $[Mn(phen)_2(C_5O_5)]$. The dihedral angle between the two phen planes for the title compound is 85.3 (1)° and the croconate and phen planes are also effectively perpendicular, with a dihedral angle of 87.7 (1)°. Compared with our previous reported result(Chen *et al.* 2005, 2007, 2008), the crystal growth method not only influence crystal packing motif, but also have effect on the moleular configuration. The crystal of $[Zn(phen)_2(C_5O_5)]$, $[Co(phen)_2(C_5O_5)]$ and $[Ni(phen)_2(C_5O_5)]$ are grown by hydrothermal method while the cyrstal of $[Cu(phen)_2(C_5O_5)]$ and $[Mn(phen)_2(C_5O_5)]$ are obtained by solvent evaporation under room temperature. Correspondingly, the crystal packing motif for crystal of Ni, Co, and Zn complexes are P_{bcn} , while it is C2/c for Cu and Mn complexes. As for the molecular configuration, the dihendral angles between the two phen planes for the complexes of Zn, Co, Ni are 87.7 (1)°, 85.7 (1)°, 86.0 (1)° which are almost perpendicular to each other, but they are 46.5 (1)° and 40.7 (1)° for Cu and Mn complexes.

According to the Jahn-teller effect theotry (if a d-orbital of a transiton metal ion is empty or full-filled and the other equivalent orbital is half full-filled, the coordinate enviorment of the transition metal ion will be distorted to form a more stable configuration), Cu^{2+} and Mn^{2+} have a strong tendency to Jahn-teller distortion while Zn^{2+} and Ni^{2+} are not. So, the local polyhedral $MN_4O_2(M=Zn, Co, Ni)$ in their complexes are close to the octahedral while $MN_4O_2(M=Mn, Cui)$ in their complexes are severely distorted from the octahedral. In the tiltle comound, the values of the angles subtended by the bidentate at zinc atom [77.37 (6)°] deviate significantly from the ideal vaue of 90° due to the small bite size of the five-memberbered plannar chelate rings.

As shown in Fig.2, the dipole moments of $[Zn(phen)_2(C_5O_5)]$ are arranged alternatively along +b and-b directions. There are short contacts between the phen groups and the O atoms of the croconate [*e.g.* C(6)—H(6)···O(1) (*x*, -*y*, -1/2 + *z*) and C(11)—H(11)···O(3)(-1/2 + *x*, -1/2 + *y*, 3/2 - *z*), which probably stablize the crystal structure.

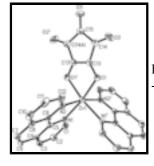

Experimental

 $[K_2(C_5O_5)](0.10 \text{ g})$ and $Zn(CH_3COO)_2.2H_2O$ (0.10 g) were dissolved in solvent of water 15 ml. The mixture was heated to 340–350 K under continuous stirring for 20 min. To the resulting yellow solution, an ethanol solution (10 ml) of 1,10phenanthroline (0.1 mol/*L*) was added to cause an immediate precipation of yellow microcrystal. After the solutions were left to stand at room temperature for 30 minutes, they were collected by filter suction, washed with water. Then the obtained precipation and 15 ml water was placed in the teflon liner of an autoclave, which was sealed and heated to 433 K for 48 h, cooled at speed of 10 K/min, whereupon yellow block of $[Zn(phen)_2(C_5O_5)]$ were obtained.

Refinement

All H atoms were geometrically fixed and allowed to ride on their attached atoms, which C—H = 0.93 Å and $U_{iso}(H)$ = 1.2 $U_{eq}(C)$.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted *R*-factor *wR* and goodness of fit *S* are based on F^2 , conventional *R*-factors *R* are based on *F*, with *F* set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating *R*-factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. *R*-factors based on F^2 are statistically about twice as large as those based on *F*, and *R*- factors based on ALL data will be even larger.
