Received 4 December 2008; accepted 15 December 2008

Key indicators: single-crystal X-ray study; $T = 150\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$; R factor = 0.046; wR factor = 0.168; data-to-parameter ratio = 13.3.

The title compound, $\text{C}_{12}\text{H}_{13}\text{ClO}_2$, was prepared by the direct asymmetric intermolecular aldol reaction of cyclopentanone and 4-chlorobenzaldehyde catalysed by L-tryptophan in water. The absolute molecular structure was determined to be a racemic twin with 91% ($2R,3R$) isomer and 9% of the ($2S,3S$) form. In the crystal structure, the molecules are connected into a one-dimensional chain along the a axis through the formation of intermolecular $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds. Further, non-conventional $\text{C}-\text{H}\cdots\text{O}$ and $\text{C}-\text{H}\cdots\pi$ contacts are observed in the structure, which consolidate the crystal packing.

Comment

The direct asymmetric aldol reaction is one of the most important C—C bond-forming reactions (Notz *et al.*, 2004.). It is not surprising that a large number of catalysts and methods have been developed to achieve efficient adducts with high diastereo- and enantioselectivities (Córdova *et al.* 2006; Torii *et al.* 2004.). Our primary results demonstrating that acyclic amino acids could catalyze the direct stereoselective aldol reaction in water micelles (Deng & Cai, 2007). In this contribution, as an extension to our previous studies, we report the synthesis and crystal structure of the title compound.

In the title compound (Fig. 1.), the bond lengths and angles are within ranges as reported by Li (2007). The structural analysis reveals that the absolute molecular structure was a (2*R*, 3*R*)- isomer. The most striking feature of the title compound is the interesting arrangement of the title molecules, which connect each other to form a one-dimension chain along the α axis by intermolecular O—H \cdots O hydrogen bonds (Fig. 2). Furthermore, the weak non-conventional intermolecular C—H \cdots π contact is observed, in which C5—H5A is donor and the chlorophenyl ring Cg2 (C1, C2, C3, C4, C12, C5) is π acceptor (Umezawa *et al.*, 1999). This contact, with additional intermolecular C—H \cdots O interactions (Nangia *et al.* 2002), further consolidate the crystal packing. Details of hydrogen bonds are given in Table 1.

Experimental

4-chlorobenzaldehyde (71 mm g, 0.5 mmol) and cyclopentanone (0.5 ml) was added to a solution of L-tryptophan (30.6 mg, 0.15 mmol) and pure water (0.5 ml) at room temperature. The mixture was stirred, monitored by TLC. The mixture was quenched with a saturated aqueous NaHCO₃ solution and extracted by ethyl acetate (3× ml). The resulting solvent was removed *in vacuo* to yield the crude product. Purification by silica gel chromatography using 100~200 mesh ZCX II eluted by hexane-ethyl acetate (3:1, *v/v*) gave the yellow solid (70 mg, yield 63%). The crystalline compound was obtained through the slow volatilization of ethyl acetate containing the title compound.

Refinement

All H atoms were positioned geometrically and treated as riding, with C—H bond lengths constrained to 0.95 Å (aromatic CH), 0.99 Å (methylene CH₂), or 0.92 Å (hydroxy), and with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ or $1.5U_{\text{eq}}(\text{methylene C})$. Moreover, the Flack parameter was refined as 0.09 (3) and indicates a possible racemic twin of about 10%. This may be because the number of measured Friedel pairs is relatively low. 572 Friedel pairs were measured, which is a fraction of measured Friedel pairs of 0.419, as indicated in the check.cif of PLATON (Spek, 2003).

$S = 1.14$	$\Delta\rho_{\max} = 0.34 \text{ e } \text{\AA}^{-3}$
1936 reflections	$\Delta\rho_{\min} = -0.52 \text{ e } \text{\AA}^{-3}$
146 parameters	Extinction correction: none
Primary atom site location: structure-invariant direct methods	Absolute structure: Flack (1983), 572 Friedel pairs
Secondary atom site location: difference Fourier map	Flack parameter: 0.09 (3)

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
