## A second modification of poly[diaquadi-$\mu$-citrato(3-)-trizinc(II)]

Xiang-He Li, Wei-Lin Chen and En-Bo Wang*<br>Department of Chemistry, Northeast Normal University, Changchun 130024, People's Republic of China<br>Correspondence e-mail: wangenbo@public.cc.jl.cn

Received 3 April 2008; accepted 5 September 2008

Key indicators: single-crystal X-ray study; $T=298 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.003 \AA$; $R$ factor $=0.027 ; w R$ factor $=0.066 ;$ data-to-parameter ratio $=13.7$.

A second modification of the zinc(II) coordination polymer with citric acid, $\left[\mathrm{Zn}_{3}\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}_{7}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{\mathrm{n}}$ or $\left[\mathrm{Zn}(\text { citrate })_{2^{-}}\right.$ $\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$, has been synthesized under hydrothermal conditions by reacting zinc acetate with citric acid. The structure contains two unique Zn atoms, one with a distorted octahedral coordination and located on an inversion centre, and one with a distorted tetrahedral coordination. The $\mathrm{ZnO}_{6}$ and $\mathrm{ZnO}_{4}$ units are linked into layers extending parallel to (010).

## Comment

The design and synthesis of coordination polymers with extended frameworks has drawn great attention due to their potential applications in catalysis, ligand exchange and their physical properties (Yaghi et al., 1996; Bourne et al., 2001). The coordination chemistry of biologically relevant transition metal ions toward citric acid has been widely investigated (Liu et al., 2005; Xie et al., 2005.) In this work, a new zinc(II) coordination polymer with citric acid (1) has been synthesized. The structure of (1) is reported here, shown in Fig. 1.

In (1) a compact layered structure is evident. An isolated $\mathrm{Zn}(1)$ ion is situated on an inversion center and is linked with two symmetry-related citrate ligands. It is surrounded in a distorted octahedral coordination by six oxygen atoms from four carboxylate oxygen atoms and two hydroxyl oxygen atoms from the citrate ligands. The $\mathrm{Zn}(1)-\mathrm{O}$ distance are in the range of $2.0707(18)-2.1029(18) \AA$. The $\mathrm{Zn}(2)$ ion is coordinated by three oxygen atoms from three carboxylate ligands and an oxygen from a water molecule in a distorted tetrahedral coordination. The $\mathrm{Zn}(2)$ — O distances are in the range of 1.9475 (19) -2.0141 (19) $\AA$. The $\mathrm{ZnO}_{6}$ and $\mathrm{ZnO}_{4}$ units are linked into a layer structure extending parallel to the $a c$ plane (Fig. 2).

Recently, another polymorph of a compound with this composition has been reported by Wu (2008). The main structural difference of (1) and the first polymorph is the coordination of the zinc cations. In the first polymorph solely $\mathrm{ZnO}_{6}$ units are present. However, by linking the structural units, a layered structure is likewise formed in this polymorph.

## Experimental

Compound (1) was prepared from a weak acidic mixture of zinc acetate ( $0.255 \mathrm{~g}, 1 \mathrm{mmol})$, citric acid ( $0.49 \mathrm{~g}, 1.5 \mathrm{mmol}$ ) and a 15 ml alcohol/water mixture, which was sealed in a 30 ml Teflon-lined steel vessel and kept at 433 K under autogenously pressure for three d. After cooling, yellow crystals were isolated and air-dried with a yield of approximately $63 \%$.

## Refinement

All H-atoms bound to carbon were refined using a riding model with $\mathrm{d}(\mathrm{C}-\mathrm{H})=0.97 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{C})$. H atoms of the water molecule were located in difference maps and refined isotropically with $\mathrm{d}(\mathrm{O}-\mathrm{H})=0.85 \AA$ and $U_{\text {iso }}(\mathrm{H})=$ $1.5 U_{\mathrm{eq}}(\mathrm{O})$.

## Figures

Fig. 1. A view of the molecule of (1). Displacement ellipsoids are drawn at the $70 \%$ probability level. Hydrogen atoms are drawn as small circles of arbitrary radius.

## supplementary materials

Fig. 2. 2-D packing arrangement of (1) viewed along the $b$ axis. Color codes: Zn (yellow), O (red), C (grey). Hydrogen atoms are omitted for clarity.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$ factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.

The highest residual peak, $0.871 \mathrm{e} \mathrm{A}^{3}$, is close to O (1) (with the distance of $c a 0.967 \mathrm{~A}$ ), to $\mathrm{C}(1)$ with the distance of $c a 1.296 \mathrm{~A}$, but featureless. The deepest hole is $-0.604 \mathrm{e} \mathrm{A}^{3}$.
