Received 19 February 2009; accepted 20 February 2009

Key indicators: single-crystal X-ray study;  $T = 293$  K; mean  $\sigma(N-C) = 0.005$  Å;  $R$  factor = 0.050;  $wR$  factor = 0.141; data-to-parameter ratio = 22.8.

In the centrosymmetric dimeric title compound,  $[Cu_2(C_3H_6NS_2)_4]$ , the Cu<sup>II</sup> atom is five-coordinate in a square-pyramidal environment. The basal coordination positions are occupied by four S atoms from two dimethyldithiocarbamate ligands and the apical coordination position is occupied by an S atom also bonded to the other Cu atom.

### Comment

Research into transition metal complexes has been rapidly expanding because of their fascinating structural diversity, as well as their potential applications as functional materials and enzymes (Noro *et al.*, 2000; Yaghi *et al.*, 1998). Dialkyldithiocarbamates anions, which are typical sulfur ligands, acting as monodentate, bidentate or bridging ligands, are often chosen for the preparation of a considerable structural variety of complexes (Engelhardt *et al.*, 1988; Fernández *et al.*, 2000; Koh, *et al.*, 2003). We report here the crystal structure of the title copper(II) complex, (I), containing a dimethyldithiocarbamate ligand.

The crystal structure of (I) is built up by dimeric entities of Cu<sup>II</sup> complex (Fig. 1). The coordination geometry of Cu<sup>II</sup> ion is described as a distorted square-pyramid. The basal coordination positions are occupied by four S atoms from two dimethyldithiocarbamate ligands. Each bridging S atom simultaneously occupies an equatorial coordination site on one Cu<sup>II</sup> ion and apical site on the other Cu<sup>II</sup>. The axial Cu—S bond distance is longer than the equatorial Cu—S ones (Table 1).

### Experimental

A mixture of Cu(Ac)<sub>2</sub>.H<sub>2</sub>O (0.04 g, 0.2 mmol) and NaS<sub>2</sub>CNMe<sub>2</sub>.2H<sub>2</sub>O (0.04 g, 0.2 mmol) was stirred in DMF (15 ml) at 313 K. 2-PrOH was diffused into the resulting solution, yielding single crystals of (I).

### Refinement

H atoms were positioned geometrically and refined as riding atoms, with C—H = 0.96 Å,  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ .

### Figures

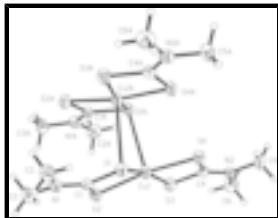

Fig. 1. The molecular structure of (I) with 30% probability displacement ellipsoids (arbitrary spheres for H atoms). [Symmetry code: A 1 -  $x$ ,  $y$ ,  $1/2 - z$ .]

## Refinement

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: inferred from neighbouring sites
$R[F^2 > 2\sigma(F^2)] = 0.050$	H-atom parameters constrained
$wR(F^2) = 0.141$	$w = 1/[\sigma^2(F_o^2) + (0.0741P)^2 + 4.6176P]$ where $P = (F_o^2 + 2F_c^2)/3$
$S = 1.07$	$(\Delta/\sigma)_{\text{max}} < 0.001$
2685 reflections	$\Delta\rho_{\text{max}} = 0.44 \text{ e \AA}^{-3}$
118 parameters	$\Delta\rho_{\text{min}} = -0.58 \text{ e \AA}^{-3}$
Primary atom site location: structure-invariant direct methods	Extinction correction: none

## Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -

factors(gt) etc. and is not relevant to the choice of reflections for refinement. *R*-factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and *R*-factors based on ALL data will be even larger.
