Received 16 December 2008; accepted 9 February 2009

Key indicators: single-crystal X-ray study;  $T = 297\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.006\text{ \AA}$ ;  $R$  factor = 0.041;  $wR$  factor = 0.097; data-to-parameter ratio = 16.7.

The title compound,  $\text{C}_{16}\text{H}_{18}\text{O}_2\text{P}_2$ , possesses two stereogenic P atoms and shows a distorted *s-cis* conformation of each  $\text{O}=\text{P}—\text{C}=\text{C}$  moiety. This has been suggested on the basis of the stereochemical result of 1,3-dipolar cycloadditions with nitrones and is now confirmed by the present crystal structure analysis. There are two crystallographically independent molecules in the asymmetric unit.

### (*S<sub>p</sub>,S<sub>p</sub>*)-(−)-(E)-1,2-Bis(methylphenylphosphinoyl)ethene

**H. Butenschön, N. Vinokurov, I. Baumgardt and K. M. Pietrusiewicz**

#### Comment

Optically active P-stereogenic 1,2-diphosphinoethanes constitute an important class of chiral bidentate ligands of great practical utility in the field of asymmetric catalysis (Crepé & Imamoto, 2003, Glueck, 2008, Knowles, 1983, 2002). The corresponding P-stereogenic diphosphane dioxides, which are the most direct precursors to such ligands, have recently been shown to be easily accessible through a simple conjugate addition of secondary phosphine oxides to the homochiral (−)-(S<sub>p</sub>)-methylphenylphosphine oxide oxide (Pietrusiewicz & Zablocka, 1988). Recently, we reported on the synthesis of (*S<sub>p</sub>,S<sub>p</sub>*)-(−)-(E)-ethene-1,2-diylbis[methyl(phenyl)phosphine] dioxide (**1**) by the homo cross-metathesis reaction of (S)-methylphenylvinylphosphine oxide (Demchuk *et al.*, 2003, Vinokurov *et al.*, 2008, Vinokurov *et al.*, 2006) and then studied the reactivity of **1** in 1,3-dipolar cycloadditions with acyclic nitrones to achieve new bidentate P-stereogenic phosphane ligands after stereospecific reduction (Vinokurov *et al.*, 2008).

Although we have recently postulated the di-*s*-cis conformation of **1** as the reactive conformation in the thermal 1,3-dipolar cycloaddition, no experimental evidence with regard to the conformation of **1** has yet been reported. However, the structure of the related (−)-(S<sub>p</sub>)-methylphenylphosphine oxide (Pietrusiewicz *et al.*, 1991) and (+)-(R<sub>p</sub>)-(tert-butylvinylphosphinoyl)benzene have recently been reported (Szmigelska *et al.*, 2006). Herein, we describe the solid state structure of (*S<sub>p</sub>,S<sub>p</sub>*)-(−)-(E)-ethene-1,2-diylbis[methyl(phenyl)phosphine] dioxide (**1**), which has been obtained by a single-crystal X-ray structure analysis.

The molecular structure of **1** is displayed in Fig. 1. The absolute configuration of the stereogenic centers has not been determined crystallographically but is evident from that of the starting material (Pietrusiewicz *et al.*, 1984, Pietrusiewicz *et al.*, 1991) as well as from the crystal structure analysis of a cycloaddition product (Vinokurov *et al.*, 2008). The largest substituents of each phosphorus atom are placed in the most distant zigzag positions, and the P1=O1 and P2=O2 dipoles are oriented in opposite directions relative to one another. The deviation from planarity of the O=P—C=C—P=O is reflected by the torsional angles given in Table 1.

As typical for compounds of type R<sub>3</sub>P=O deformations of the tetrahedral environment of the P atoms cause an increase of the O—P—C and the simultaneous decrease of the C—P—C valency angles. The values observed fall in the range of 110.28 (15) - 115.80 (17)<sup>o</sup> and 101.69 (17) - 107.26 (15)<sup>o</sup> for P1 and, 110.87 (15)<sup>o</sup> - 114.73 (15)<sup>o</sup> and 102.42 (17) - 107.94 (14)<sup>o</sup> for P2, respectively.

DFT calculations show the observed conformation to be more stable than the corresponding di-*s*-trans conformation by 16.54 kJ/mol (TURBOMOLE 5.7 Method BP86/SV(P)).

#### Experimental

For the preparation of (*S<sub>p</sub>,S<sub>p</sub>*)-(−)-(E)-1,2-bis(methylphenylphosphinoyl)ethene (**1**) see Vinokurov *et al.* (2006).

## Refinement

Note: The asymmetric unit contains two crystallographically independent molecules, one of which is presented here. H atoms were positioned geometrically and refined using a riding model with C—H = 0.93–0.96 Å and with  $U_{\text{iso}}(\text{H}) = 1.2$  (1.5 for methyl groups)  $\times U_{\text{eq}}(\text{C})$ .

## Figures

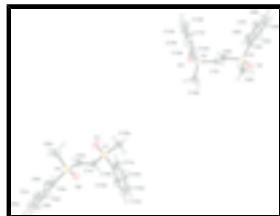

Fig. 1. Structure of (1) in the crystal with atom labels and 50% probability displacement ellipsoids for non-H atoms.

1 restraint	Absolute structure: Flack (1983), 2656 Friedel pairs
Primary atom site location: structure-invariant direct methods	Flack parameter: 0.01 (9)
Secondary atom site location: difference Fourier map	

## *Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
