Received 9 October 2008; accepted 10 March 2009

Key indicators: single-crystal X-ray study; $T = 293\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$; R factor = 0.032; wR factor = 0.097; data-to-parameter ratio = 14.5.

The title complex, $\text{H}_3\text{O}^+\cdot\text{NH}_3\text{C}(\text{CH}_3)(\text{PO}_3\text{H})_2^-$, contains a hydroxonium ion and an $\text{NH}_3\text{C}(\text{CH}_3)(\text{PO}_3\text{H})_2^-$ anion. The three H atoms of H_3O^+ form a pseudo-tetrahedron by being distributed over four positions with occupation factors of 0.75. Multiple N—H···O and O—H···O hydrogen bonds in the crystal structure form an intricate three-dimensional supramolecular network.

Hydroxonium 1-ammonioethane-1,1-diyldiphosphonate

M. Li, W. Wen, W. Ha and L. Chang

Comment

Organophosphonic acids and their compounds have attracted tremendous interest. A series of phosphonate hybrid materials have been prepared and show potential applications in catalysts, sensors, sorbents, magnetic and luminescent materials. Such materials also illustrate a variety of structures from one-dimensional chains, two-dimensional layers to three-dimensional porous frameworks. (Finn *et al.*, 2003). Introduction of some functional groups to phosphonic acids, such as crown ether, $-COOH$, $-OH$, $-NR_2$ or mixed groups will modify their complexing ability and construct a great number of novel phosphonates (Clearfield, 2002). Compared with other phosphonic acids, 1-aminoethylidene-1,1-diphosphonic acid (AEDPH₄) is easier to synthesize. However, little attention has been paid to the structural study of metal-AEDP compounds (Yin *et al.*, 2005; Ding *et al.*, 2006). In our recent paper, it is found that AEDPH₄ is inclined to transfer one proton to the amino group, which is in agreement with Fernández's results on similar bisphosphonates. (Li *et al.*, 2008; Fernández *et al.*, 2003). Deprotonation of it will result in predictable hydrogen aggregates from stronger P—O—H···O—P to weaker C—H···O hydrogen bonds. Herein, we report its structure, (I).

The asymmetric unit of (I) is built up from one deprotonated AEDPH₃ anion and a disordered H₃O⁺ cation, which are linked through four types of Ow-H···O hydrogen bonds (Fig. 1, Table 1). Two of the four protons of phosphonates are used in protonation, one for the amino group, the other for the H₃O⁺ cation. The combination of different hydrogen bond interactions, N-H···O and O-H···O results in the formation of an intricate three dimensional supramolecular network (Fig. 2, Table 1).

Experimental

The AEDPH₄ was synthesized according to the US Patent 4239695 (Chai *et al.*, 1980). It was crystallized directly from the AEDPH₄ aqueous solution. When the mixture was heated for 24 h, colorless crystals were obtained.

Refinement

All H atoms attached to C and N atoms were fixed geometrically and treated as riding with C—H = 0.96 Å (C), N—H = 0.89 Å with U_{iso}(H) = 1.5U_{eq}(C,N). The H atoms of hydroxyl were located in difference Fourier maps and included in the subsequent refinement.

The three hydrogen atoms of the H₃O⁺ cation are statistically distributed over four positions with occupation factor of 0.75, building a pseudo tetrahedron.

Primary atom site location: structure-invariant direct methods	Extinction coefficient: 0.023 (2)

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
