Received 8 August 2009; accepted 27 August 2009

Key indicators: single-crystal X-ray study;  $T = 130\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$ ;  $R$  factor = 0.032;  $wR$  factor = 0.085; data-to-parameter ratio = 14.3.

In the structure of the 1:1 proton-transfer compound of 1,10-phenanthroline with 4,5-dichlorophthalic acid,  $\text{C}_{12}\text{H}_9\text{N}_2^+ \cdot \text{C}_8\text{H}_3\text{Cl}_2\text{O}_4^-$ , determined at 130 K, the 1,10-phenanthrolinium cation and the hydrogen 4,5-dichlorophthalate anion associate through a single  $\text{N}-\text{H} \cdots \text{O}_{\text{carboxyl}}$  hydrogen bond giving discrete units which have no extension except through a number of weak cation  $\text{C}-\text{H} \cdots \text{O}_{\text{anion}}$  associations and weak cation–anion aromatic ring  $\pi-\pi$  interactions [minimum centroid–centroid separation =  $3.6815(12)\text{ \AA}$ ]. The anions are essentially planar "[maximum deviation  $0.214(1)\text{ \AA}$  (a carboxyl O)] with the *syn*-related H atom of the carboxyl group, forming a short intramolecular  $\text{O}-\text{H} \cdots \text{O}_{\text{carboxyl}}$  hydrogen bond.

## 1,10-Phenanthrolin-1-ium 2-carboxy-4,5-dichlorobenzoate

G. Smith, U. D. Wermuth and J. M. White

### Comment

The 1:1 proton-transfer compounds of 4,5-dichlorophthalic acid (DCPA) with the aromatic nitrogen Lewis bases commonly have low-dimensional hydrogen-bonded structures (Smith *et al.*, 2007, 2008a, 2008b, 2009a, 2009b; Bozkurt *et al.*, 2006; Mallinson *et al.*, 2003). In the two-dimensional examples the DCPA anions assume non-planar conformations and form into sheet substructures which in the case of the compounds with the *meta*- and *para*-aminobenzoic acids (Smith *et al.*, 2008b) are extended into three-dimensional frameworks through peripheral cyclic head-to-head carboxylic acid hydrogen-bonding associations. However, with the majority of the structures, e.g. the brucinium salt (Smith *et al.*, 2007), the DCPA anions are essentially planar with short intramolecular carboxylic acid O–H···O<sub>carboxyl</sub> hydrogen bonds. These features were therefore expected and found in the 1:1 proton-transfer compound of DCPA with 1,10-phenanthroline, (I), reported here.

In (I), a single N<sup>+</sup>–H···O<sub>carboxyl</sub> hydrogen bond links the phenanthroline cation and the DCPA anion (Fig. 1). A weak aromatic ring C–H···O<sub>carboxyl</sub> interaction (Table 1) completes an asymmetric R<sub>2</sub><sup>2</sup>(7) cyclic association (Etter *et al.*, 1990). Three additional anion C–H···O interactions represent the only structure extensions present. Some overlap is present between the anion aromatic ring (C1–C6) and one six-membered ring of the cation (N10A, C9A, C8A, C7A, C6A, C14A) [minimum ring centroid separation, 3.6815 (12) Å] (Fig. 2), giving weak π–π stacking interactions (Fig. 3). The DCPA anion is essentially planar [torsion angles C2–C1–C11–O11, -168.30 (16)°; C1–C2–C21–O22, -179.53 (16)°], and exhibits a short intramolecular O–H···O<sub>carboxyl</sub> hydrogen bond [2.4054 (19) Å]. Associated with this bond is a significant distortion of the *exo*-C1 and C2 bond angles [C1–C2–C21, 128.55 (15)° and C2–C1–C11, 129.18 (16)°]. This and a lengthening of the C1–C11 and C2–C21 bonds [1.538 (3) and 1.536 (3) Å] is common to the planar DCPA anions in the series of 1:1 proton-transfer compounds [angle range: 127.88 (16)° in the nicotinamide salt (Smith *et al.*, 2009a) to 129.27 (14)° in the 8-aminoquinoline salt (Smith *et al.*, 2008a); bond length range: 1.523 (3)–1.535 (3) Å, both in the brucinium salt (Smith *et al.*, 2007)].

### Experimental

The title compound (I) was synthesized by heating 1 mmol quantities of 1,10-phenanthroline and 4,5-dichlorophthalic acid in 50 ml of 95% ethanol for 10 min under reflux. After concentration to *ca.* 30 ml, partial room-temperature evaporation of the hot-filtered solution gave colourless plates (m.p. 464–465 K) suitable for data collection.

### Refinement

Hydrogen atoms potentially involved in hydrogen-bonding interactions were located by difference methods and their positional and isotropic displacement parameters were refined. Other H atoms were included in the refinement at calculated positions [C–H, 0.93 Å] and treated as riding models with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ .

 $k = -9 \rightarrow 9$   
 $l = -23 \rightarrow 21$

### *Refinement*

Refinement on  $F^2$   
Least-squares matrix: full  
 $R[F^2 > 2\sigma(F^2)] = 0.032$   
 $wR(F^2) = 0.085$   
 $S = 1.04$   
3734 reflections  
261 parameters  
1 restraint  
Primary atom site location: structure-invariant direct methods  
Secondary atom site location: difference Fourier map

Hydrogen site location: inferred from neighbouring sites  
H atoms treated by a mixture of independent and constrained refinement  
 $w = 1/[\sigma^2(F_o^2) + (0.053P)^2 + 0.0522P]$   
where  $P = (F_o^2 + 2F_c^2)/3$   
 $(\Delta/\sigma)_{\max} = 0.001$   
 $\Delta\rho_{\max} = 0.30 \text{ e } \text{\AA}^{-3}$   
 $\Delta\rho_{\min} = -0.19 \text{ e } \text{\AA}^{-3}$   
Extinction correction: none  
Absolute structure: Flack (1983), 1564 Friedel pairs  
Flack parameter: 0.00 (4)

### *Special details*

**Geometry.** Bond distances, angles etc. have been calculated using the rounded fractional coordinates. All su's are estimated from the variances of the (full) variance-covariance matrix. The cell e.s.d.'s are taken into account in the estimation of distances, angles and torsion angles

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ - factors based on ALL data will be even larger.
