Received 12 August 2009; accepted 10 September 2009

Key indicators: single-crystal X-ray study; $T = 200\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$; R factor = 0.049; wR factor = 0.136; data-to-parameter ratio = 15.3.

The title compound, $2\text{C}_{17}\text{H}_{20}\text{N}_2\text{O}\cdot\text{CH}_2\text{Cl}_2$, was obtained by *N*-oxidation of the parent formamidine with *m*-chloro-peroxybenzoic acid (*m*-CPBA). This is the first use of the above-mentioned synthetic route for the preparation of hydroxyamidines. The title compound crystallizes as a cyclic dimer resulting from the presence of $\text{O}-\text{H}\cdots\text{O}$ and $\text{N}-\text{H}\cdots\text{N}$ hydrogen bonds.

M. Cibian, S. Derossi and G. S. Hanan

Comment

Hydroxyamidines have long been known to act as bidentate ligands that form stable 5-membered chelate rings with metal ions, and have been extensively studied as sequestrating agents for metals and in pharmacology (Kharsan & Mishra, 1980; Briggs *et al.*, 1976). However, their role as ligands for coordination and supramolecular chemistry has so far received scarce attention (Krajete *et al.*, 2004). This is somewhat surprising as they show good electronic delocalization and interesting design possibilities involving both the coordination geometry and the functionalization of the backbone. These properties make hydroxyamidines and their complexes interesting candidates for incorporation into supramolecular assemblies. In this paper we studied the behaviour of the title compound, comprising the ligand *N*-hydroxy-*N,N'*-bis(2,6-dimethylphenyl)formamidine in the solid state. As exemplified by Fig. 1, amidines present two sites for H-bonding interaction: the hydroxy group and the N *sp*² as H-bond donor and acceptor, respectively. It is therefore plausible to expect that the molecule will dimerize in a cyclic self-complementary H-bonded O—H···N fashion.

The asymmetric unit of compound **1** presents two inequivalent molecules of **1** and one molecule of dichloromethane. The two molecules of the ligand unexpectedly form a cyclic dimer through a pair of H-bonding interactions O—H···O and one N—H···N. In the dimer, one formamidine is present in its neutral form, N=C—N—OH, while the second appears as the zwitterionic form, with the negative charge on the oxygen and the positive charge delocalized between the two nitrogen atoms, leading to two resonance forms: NH⁺=C—N—O[−] and NH—C—N⁺=O[−] (see scheme). Hence, the resulting bridges can be best described as O—H···O[−] and N—H···N H-bonds. The O—H···O[−] interaction has been previously reported in the analogous crystal structure of a benzamidine system by Krajete *et al.* (2004). In that case, however, the ligand dimerizes *via* a single H-bond. The assignment of neutral and zwitterionic moiety [N(4)—C(2)—N(3)—O(2) and N(2)—C(1)—N(1)—O(1), respectively] is consistent with the position of the hydrogen atoms observed in the crystal structure, however, none of the N—C distances has a clear character of single or double bond, ranging from 1.291 to 1.330 Å.

The planes of all the aromatic rings are tilted with respect to the O—N—C—N plane: in the neutral molecule the tilt angles are 70.5 (1) and 80.2 (1)^o, while in the zwitterionic molecule these range from 87.6 (1) to 87.7 (1)^o. This conformation is probably achieved to release the O—N—C—N backbone from the steric bulk of the methyl groups on the 2,6 position of the phenyl groups, and was also noticed in the structures of benzamidines studied by Krajete *et al.* (2004). The 10-atom cycle formed by the two molecules exhibits a highly distorted geometry, the planes of the N—C—N—O backbones forming an angle of 42.4 (1)^o, while for the O—H···O[−] H-bond the torsion angle N(1)—O(1)···O(2)—N(3) is 157.4 (2)^o.

Structural and photophysical studies of the coordination compounds of the formamidine here described are currently in progress and will be subject of a future publication.

supplementary materials

Experimental

The title compound was obtained by *N*-oxidation with *m*-chloro-peroxybenzoic acid (*m*-CPBA) of the parent formamidine; the latter was prepared according to the procedure of Krahulic *et al.* (2005). To a solution of *N,N'*-bis(2,6-dimethylphenyl)-formamidine (1.0 g, 3.96 mmol) in 20 ml of dichloromethane, was added dropwise a solution of *m*-CPBA (0.9 g, 3.96 mmol) in 20 ml of the same solvent. The reaction mixture was stirred for 30 minutes at room temperature and successively washed with an aqueous solution of K₂CO₃ (5%) (2 x 25 ml) and of saturated NaHCO₃ (2 x 25 ml). The combined organic fractions were dried over anhydrous Na₂SO₄ and filtered. The solvent was removed by evaporation, to afford a crude off white product. Recrystallization in DCM/ hexane (1:1) at -10°C yielded colourless X-ray quality crystals. Yield 92%.

1H NMR (DMSO-d6, 300 MHz, δ, p.p.m.): 7.80 (s, 1H), 7.20–7.10 (m, 3H), 7.00 (d, 2H), 6.88 (t, 1H), 3.50 (bs, 1H, OH), 2.31 (s, 6H), 2.16 (s, 6H).

Refinement

N-bound and O-bound H atoms were located in a difference Fourier map and refined. All other H atoms were placed in calculated positions, with C–H = 0.93–0.99 Å, and refined using a riding model, with *U*_{iso}(H) = 1.2 or 1.5 *U*_{eq}(C).

Figures

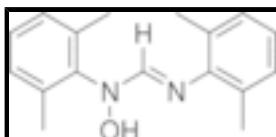

Fig. 1. A schematic view of the *N*-hydroxy-*N,N'*-bis(2,6-dimethylphenyl)formamidine ligand.

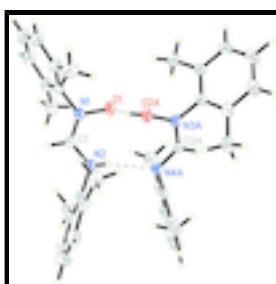

Fig. 2. The molecular structure of the title compound, 1. Displacement ellipsoids are shown at 30% probability levels. CH₂Cl₂ is not shown for clarity.

Secondary atom site location: difference Fourier map	

Special details

Experimental. X-ray crystallographic data for **1** were collected from a single-crystal sample, which was mounted on a loop fiber. Data were collected using a Bruker smart diffractometer equipped with an *APEX II* CCD Detector, a graphite monochromator. The crystal-to-detector distance was 5.0 cm, and the data collection was carried out in 512 x 512 pixel mode. The initial unit-cell parameters were determined by a least-squares fit of the angular setting of strong reflections, collected by a 10.0 degree scan in 33 frames over four different parts of the reciprocal space (132 frames total).

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

supplementary materials

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
