Received 10 November 2009; accepted 10 November 2009

Key indicators: single-crystal X-ray study; $T = 120\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.002\text{ \AA}$; R factor = 0.048; wR factor = 0.122; data-to-parameter ratio = 11.7.

The title compound, $\text{C}_{14}\text{H}_{11}\text{NO}_2$, features an essentially planar molecule, the r.m.s. deviation for the 17 non-H atoms being 0.035 \AA . This conformation is stabilized by an intramolecular $\text{O}-\text{H}\cdots\text{N}$ hydrogen bond that results in the formation of an $S(6)$ ring. In the crystal structure, methylene–hydroxy $\text{C}-\text{H}\cdots\text{O}$ contacts result in a supramolecular chain aligned along the b axis.

Comment

Reactions of various arene-aldehydes, ArCHO, *e.g.* Ar = Ph, thien-2-yl and pyridin2-yl, with ammonia, under basic conditions, have provided rac-2,4,5-Ar₃-4,5-dihydro-1*H*-imidazoles, **1** (Hunter & Sims, 1972*a*, *b*; Corey, & Kühnle, 1997; Larter *et al.*, 1998; Chou *et al.*, 2004), see Fig. 3, either as the kinetic product, the *cis*-isomer, or the thermodynamic product, the *trans*-isomer. We reported similar products from these aldehydes using the mixture of NH₄Cl and NEt₃ as the ammonia source in MeOH (Fernandes *et al.*, 2007). In contrast, we have found that 2-hydroxybenzaldehyde, under these conditions produced (**2**: R = H).

The reaction of 2-hydroxybenzaldehyde with ammonia had previously been studied as a function of solvent (Kitan *et al.*, 1990). Thus in C₆H₆, hexane or Et₂O, 2-HOC₆H₄CHNH was formed. In H₂O, dioxan, MeOH or EtOH solution 2-HOC₆H₄CH(NCHC₆H₄OH-2)₂ (**3**), was the product, while in MeOH with NH₄OAc and NH₄HCO₃, both **3** and **4** were formed. Earlier, it had been reported that 2-hydroxybenzaldehyde, NH₄OAc and HOAc in refluxing C₆H₆ produced **4** (Kanakarajan *et al.*, 1975). Interestingly, (**2**: R = H) has been shown to arise from the acid-catalysed decomposition of **4**, alternatively obtained as the *cyclo*-condensation product of 2-hydroxybenzaldehyde with HONH₂ (Meier *et al.*, 1979).

While the NMR spectra, in particular the two hydrogen singlet in the ¹H NMR spectrum, suggested the compound (**2**: R = H) confirmation from the X-ray structure determination was considered to be of value, particularly since treatment of 6-nitro-2-hydroxybenzaldehyde with NH₄OAc in acetic acid had been reported to give **5** (Beer *et al.*, 1948). However, no spectral details had been provided for **5**. In the light of our findings, the structure of **5** could be modified to (**2**: R = NO₂). The change from **5** to (**2**: R = NO₂) merely involves a prototropic rearrangement. Herein, the crystal and molecular structure of (**I**) [= **2**: R = H in Fig. 1] is described.

The molecular structure of (**I**), Fig. 2, is essentially planar with the RMS for the 17 non-hydrogen atoms being 0.035 Å. The maximum deviation is 0.049 (1) Å for the N1 atom. This conformation is stabilized by an intramolecular O–H···N hydrogen bond that completes an S(6) ring synthon. The most prominent interactions in the crystal structure are of the type C–H···O, Table 1, which lead to supramolecular chains along the *b* direction, Fig. 3.

Experimental

A solution of 2-hydroxybenzaldehyde (3.7 g, 0.03 mol), ammonium chloride (3 g, 0.06 mol) and triethylamine (8.1 ml, 0.06 mol) in MeOH (30 ml) was refluxed for 8 h. The solvent was removed *in vacuo*, the residue was extracted into CHCl₃, washed with water (2 x 15 ml), dried over magnesium chloride, and rotary evaporated. The pale coloured residue was recrystallized from EtOH to give colourless crystals. Anal. Calc. for C₁₄H₁₁NO₂: C, 74.65; H, 4.92; N, 6.22. Found: C, 74.32; H, 4.80; N, 6.01%. ¹H NMR (Me₂CO-d6, 400 MHz): δ 13.02 (s, 1H), 7.96 (dd, J = 1.6, 8.0 Hz, 1H), 7.41–7.37 (dt, J

supplementary materials

= 1.7, 8.0 Hz, 1H), 7.33–7.28 (*m*, 1H), 7.20–7.14 (*m*, 3H), 6.91 (*m*, 2H), 4.82 (*s*, 2H) p.p.m. ^{13}C NMR (CDCl_3 , 100 MHz): δ 134.1, 129.4, 128.1, 127.3, 126.3, 119.1, 118.0, 116.6, 44.1 p.p.m.; quaternary-C not detected.

Refinement

The C-bound H atoms were geometrically placed ($\text{C}-\text{H} = 0.95\text{--}0.99 \text{\AA}$) and refined as riding with $U_{iso}(\text{H}) = 1.2U_{eq}(\text{C})$. The hydroxyl-H was located from a difference map and refined with $\text{O}-\text{H} = 0.840\pm0.001 \text{\AA}$, and with $U_{iso}(\text{H}) = 1.5U_{eq}(\text{O})$.

Extinction coefficient: 0.031 (5)

Special details

Geometry. All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
