Received 27 January 2010; accepted 18 February 2010

Key indicators: single-crystal X-ray study; $T = 100\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.007\text{ \AA}$; R factor = 0.048; wR factor = 0.113; data-to-parameter ratio = 15.7.

In the title compound, $[\text{Zn}(\text{C}_{18}\text{H}_{39}\text{N}_3\text{O}_3)](\text{NO}_3)_2\cdot\text{H}_2\text{O}$, the coordination geometry around the central Zn^{II} atom is distorted octahedral. The hydroxyl groups in the macrocyclic ligand and water molecules are engaged in $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonding, which forms two-dimensional corrugated sheets comprising 34-membered rings. Neighbouring sheets are connected by $\text{C}-\text{H}\cdots\text{O}$ interactions.

Comment

Azamacrocycles and some of their *N*-substituted derivatives are of synthetic interest due to their unique binding properties with metal ions. The addition of different pendant arms can enhance the selectivity of the azamacrocycle for a metal cation, depending on the cavity size and on the nature of the substituents (Skerlj *et al.*, 2002). The design and synthesis of polyazamacrocycles bearing flexible pendant arms from the cyclic framework provides chemists with an opportunity to design macrocycles tailored for a specific function. This is especially the case because the pendant arms provide additional coordination sites for metal ions.

Functionalised macrocycles have been successfully employed in the synthesis of metal-chelating agents for medical applications owing to the kinetic inertness of the complexes which makes them resistant to decomplexation (Sheng *et al.*, 2007).

In the title compound (Fig. 1), the Zn^{II} atom is octahedrally coordinated. Small distortions cause the N—Zn—N angles to exceed 90° while the O—Zn—O angles measure less than 90°. The dicationic complex exhibits near *C*₃-symmetry with exception of the propylene groups in which the central CH₂ group adopts a different conformation in each sector.

The three hydroxyl groups are all engaged in hydrogen bonds. The O1—H1 and O3—H3 groups form hydrogen bonds (Table 1) with the two asymmetric nitrate counter anions and the O2—H2 group with the water molecule. This water molecule itself forms two hydrogen bonds with two other complexes. The hydrogen bonding results in the formation of two-dimensional corrugated sheets parallel to the *ac* plane. Three adjacent complex units are linked to form 34-membered rings which include ten hydrogen bonds (Fig. 2). Neighbouring sheets are loosely connected by C—H···O interactions involving one of the CH₂ groups of the triazacyclododecane.

The configuration at C11, C14 and C17 is (*S*), resulting from utilisation of enantiopure (*S*)-methyloxirane in the synthetic process which is supported by anomalous scattering.

Experimental

The chiral macrocyclic ligand 1,5,9-tris[(2*S*)-2-hydroxypropyl]-1,5,9-triazacyclododecane was prepared by treating three equivalents and a slight excess of (*S*)-methyloxirane with 1,5,9-triazacyclododecane in absolute ethanol. This solution was stirred at room temperature for 3 days. 1,5,9-Triazacyclododecane was prepared using a modified method of Richman & Atkins (1974) and Sabatini & Fabrizzi (1979).

One equivalent of Zn(NO₃)₂·6H₂O was dissolved in ethanol at 333 K with stirring. The ligand was added to the solution and it was stirred overnight. The powder which formed was filtered off and dissolved in a small quantity of *N,N*-dimethylformamide whereupon diethyl ether vapour was slowly diffused into the solution in a sealed container. Single crystals were obtained the next day.

supplementary materials

Refinement

Alkyl H atoms were positioned geometrically ($C-H = 1.00$, 0.99 and 0.98 \AA for CH , CH_2 and CH_3 groups, respectively) and allowed to ride on their parent atoms. Hydroxyl and water O–H distances were restrained to $0.85(1) \text{ \AA}$ and additional restraint $H4\cdots H5$ distance restraint of $1.37(1) \text{ \AA}$ was applied to the water molecule. $U_{\text{iso}}(\text{H})$ values were set at 1.2 times $U_{\text{eq}}(\text{C},\text{O})$ except for methyl groups where $U_{\text{iso}}(\text{H})$ was set at 1.5 times $U_{\text{eq}}(\text{C})$.

Figures

methods

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
