Key indicators: single-crystal X-ray study; $T = 100$ K; mean $\sigma(\text{C}-\text{C}) = 0.003 \text{ \AA}$; R factor = 0.057; wR factor = 0.144; data-to-parameter ratio = 28.1.

The title compound, $C_{27}H_{45}\text{Cl}$, is a second monoclinic polymorph which crystallizes in the space group $P2_1$ with four crystallographically independent molecules in the asymmetric unit. The structure was previously reported [Bernal *et al.* (1940). *Philos. Trans. R. Soc. London Ser. B*, **239**, 135–182; Vani & Vijayan (1979). *Mol. Cryst. Liq. Cryst.* **51**, 253–264], also in the space group $P2_1$, but with two unique molecules in the asymmetric unit. As in the previously reported structures, rings A and C in the molecule adopt chair conformations with half-chair conformations for rings B and D. The ring junctions B–C and C–D are *trans*, whereas the junction A–B is quasi-*trans*. In the crystal structure, molecules are arranged in a head-to-tail fashion along a and are stacked along the b axis.

A second monoclinic polymorph of 3β -chlorocholest-5-ene

M. S. Khan, O. Sulaiman, I. A. Mohamed, C. S. Yeap and H.-K. Fun

Comment

For the last seventy years the chemistry of steroids has provided one of the most interesting and thoroughly explored areas for organic chemists. The synthetic modification of naturally occurring steroids with the hope of improving pharmacological essentials has resulted in the preparation and discovery of a number of diverse pharmacologically active, potent, highly specific commercially important therapeutic agents (Doorenbos & Wu, 1968; Green *et al.*, 1978; Clinton & Manso, 1961). The cholesterol molecule in steroidal chemistry is well known as it comprises of four-ring structure of which three are six-membered cyclohexane rings and one is a five membered carbon ring (Rajnikant *et al.*, 2006). In the present work an attempt has been made to synthesize a derivative of the cholesterol molecule. Although the title compound (I) crystallized in the same monoclinic space group, $P2_1$, as previously reported (Bernal *et al.*, 1940; Vani & Vijayan, 1979), the unit cell is different.

The asymmetric unit of the title compound (I) consists of four crystallographically independent molecules whereas the previously reported structures had only two unique molecules in the asymmetric unit of a different monoclinic unit cell. As with the previously reported structures, rings A and C adopt chair conformations with half chair conformations for rings B and D (Cremer & Pople, 1975). The ring junctions B–C and C–D are *trans* whereas the junction A–B is quasi *trans*. In the crystal structure, molecules are arranged head-to-tail down *a* axis and each molecule is stacked along the *b* axis (Fig. 2).

Experimental

Freshly purified thionyl chloride (75 ml) was added gradually to cholesterol (100 g) at room temperature. A vigorous reaction ensued with the evolution of gaseous products. When the reaction slackened, the mixture was gently heated at the temperature of 325–335 K on a water bath for 1 h and then poured onto crushed ice-water mixture with stirring. The yellow solid thus obtained was filtered under suction and washed several times with ice-cooled water and air dried. Recrystallization of crude product from acetone gave (I) (94 g), m.p. 368–369 K (reported m.p. 369–370 K; Baker & Squire, 1948). It gave positive Beilstein test and a yellow colour with tetra-nitromethane in chloroform.

Refinement

All H atoms were positioned geometrically and refined using a riding model, with C–H = 0.93–0.98 Å, $U_{\text{iso}}(\text{H})$ = 1.2 or 1.5 $U_{\text{eq}}(\text{C})$. The rotating group model was applied for the methyl groups. The same U_{ij} parameters were used for atom pairs C23C/C24C and C23A/C24A. A total of 13239 Friedel pairs were used to determine the absolute configuration.

Special details

Experimental. The crystal was placed in the cold stream of an Oxford Cryosystems Cobra open-flow nitrogen cryostat (Cosier & Glazer, 1986) operating at 100.0 (1) K.

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
