Received 17 June 2010; accepted 21 June 2010

Key indicators: single-crystal X-ray study;  $T = 100\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$ ; disorder in solvent or counterion;  $R$  factor = 0.040;  $wR$  factor = 0.094; data-to-parameter ratio = 13.3.

In the structure of the title compound,  $[\text{Fe}(\text{C}_7\text{H}_7\text{N}_2\text{O}_2)_3] \cdot \text{CH}_3\text{CH}_2\text{OH}$ , the  $\text{Fe}^{\text{III}}$  atom is in a distorted octahedral  $\text{O}_6$  environment with the three hydroxamate O atoms (and the three carbonyl O atoms) arranged in a *fac* configuration and one of the hydroxamate ligands being puckered. The methyl C atom of the ethanol solvent molecule is disordered over two positions with occupancies of 0.626 (13) and 0.374 (13), respectively. The cocrystallized ethanol molecule is hydrogen bonded to one of the hydroxamate O atoms.  $\text{O}-\text{H}\cdots\text{O}$  and  $\text{N}-\text{H}\cdots\text{O}$  interactions generate infinite three-dimensional networks along [100], [010] and [001].

### ***fac*-Tris(4-aminobenzohydroxamato)iron(III) ethanol solvate**

**A. B. M. Alagha, D. Gaynor, H. Müller-Bunz, K. B. Nolan and L. Parthasarathi**

#### **Comment**

The Fe<sup>III</sup> core is in a distorted octahedral O<sub>6</sub> environment with the three 4-aminophenylhydroxamato ligands coordinated through both O-atoms to form stable five-membered chelates (Fig. 1). The complex has a *fac* geometric configuration defined by the positioning of the three hydroxamate or the three carbonyl O atoms. The Fe—O<sub>3</sub>—C<sub>8</sub>—N<sub>3</sub>—O<sub>4</sub> and Fe—O<sub>5</sub>—C<sub>15</sub>—N<sub>5</sub>—O<sub>6</sub> five membered rings are not puckered whereas the Fe—O<sub>1</sub>—C<sub>1</sub>—N<sub>1</sub>—O<sub>2</sub> ring exhibits a puckered configuration with the closest pucker descriptor being twisted on O<sub>2</sub>—Fe. The Cremer and Pople puckering parameters (Cremer & Pople, 1975) are Q<sub>2</sub> = 0.120 (2) Å &  $\varphi_2$  = 330.0 (9) $^\circ$  and the pseudorotation parameters (Rao *et al.*, 1981) are P = 130.8 (6) $^\circ$  and  $\tau(M)$  = 11.2 (1) $^\circ$  for reference bond Fe—O<sub>1</sub>. The co-crystallized ethanol molecule is hydrogen bonded to one of the hydroxamate oxygen atoms through strong O—H···O bond (O<sub>7</sub> H1O<sub>7</sub> O<sub>6</sub> interaction in Table 2). The O—H···O and N—H···O interactions (Table 2) form a set of clusters generating infinite two dimensional networks along the base vectors [0 1 0] and [1 0 0] and along the plane (0 0 1). These clusters then assemble to form infinite three dimensional networks (Fig. 2) along the base vectors [1 0 0], [0 1 0] and [0 0 1].

#### **Experimental**

FeCl<sub>3</sub>·6H<sub>2</sub>O (59.3 mg, 0.22 mmol) in water (5 ml), was added to a solution of 4-aminophenylhydroxamic acid, (100 mg, 0.66 mmol) in ethanol (15 ml). The pH of the resulting solution was then raised to 5.7 using 0.1 M NaOH solution whereupon a dark red precipitate was obtained. This was removed by filtration and the filtrate was left to stand at room temperature for two months whereupon very dark red crystals were obtained. These were collected by filtration and dried. Yield (100 mg, 0.18 mmol, 82%). Elemental analysis (%), calcd C<sub>23</sub>H<sub>27</sub>N<sub>6</sub>O<sub>7</sub>Fe: C, 49.56; H, 5.26; N, 15.08; Fe, 10.02; found C 49.01, H 5.02, N 15.03, Fe 9.77. IR (KBr Disc);  $\nu_{\text{max}}$  3345br, 3211br, 1604 s, 1525 s, 1484 s cm<sup>-1</sup>.

#### **Refinement**

All H-atoms (except those attached to the methylene and the methyl carbon atoms of the ethanol solvate) were located in difference maps and their positions and isotropic displacement parameters were freely refined. The CH<sub>2</sub> and CH<sub>3</sub> H atoms of the solvate were constrained to ride on their parent C atoms.

#### **Figures**

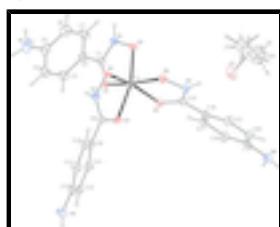

Fig. 1. The asymmetric unit of (I) with the atoms labelled and displacement ellipsoids depicted at the 50% probability level for all non-H atoms. H-atoms are drawn as spheres of arbitrary radius

#### Refinement

Refinement on $F^2$	Primary atom site location: structure-invariant direct methods
Least-squares matrix: full	Secondary atom site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.040$	Hydrogen site location: difference Fourier map
$wR(F^2) = 0.094$	H atoms treated by a mixture of independent and constrained refinement
$S = 1.06$	$w = 1/[\sigma^2(F_o^2) + (0.0438P)^2 + 0.6552P]$
	where $P = (F_o^2 + 2F_c^2)/3$

5739 reflections	$(\Delta/\sigma)_{\max} = 0.004$
433 parameters	$\Delta\rho_{\max} = 0.43 \text{ e \AA}^{-3}$
0 restraints	$\Delta\rho_{\min} = -0.31 \text{ e \AA}^{-3}$

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
