Key indicators: single-crystal X-ray study; $T = 180$ K; mean $\sigma(\text{C}-\text{C}) = 0.004$ Å; R factor = 0.041; wR factor = 0.108; data-to-parameter ratio = 13.9.

Following our continuing interest in developing new chiral phosphine-containing ferrocenyl ligands, we synthesized the title compound, $[\text{Fe}(\text{C}_5\text{H}_5)(\text{C}_{26}\text{H}_{24}\text{OPS})]$, in which there are two nearly identical molecules in the asymmetric unit. The conformation of the cyclopentadienyl (Cp) rings in each ferrocenyl group are intermediate between eclipsed and staggered, with twist angles of 16.6 (2) and 8.9 (2)°. The protecting S atom is located *endo* with respect to the substituted Cp ring. In the crystal, molecules are connected through intermolecular $\text{C}-\text{H}\cdots\pi$ interactions.

1-(Diphenylphosphinothioyl)-2-[(4-methylphenyl)methoxymethyl]ferrocene

J.-C. Daran, C. Audin, E. Deydier, E. Manoury and R. Poli

Comment

Homogenous asymmetric catalysis by transition metals has received considerable attention over the last few decades, and numerous chiral ligands and complexes allowing high efficiency reactions have been reported (Jacobsen *et al.*, 1999; Börner, 2008). In this field, chiral phosphines have played a significant role. The possibility to easily modify their electronic and steric properties by a judicious choice of their substituents has proven extremely useful to successfully optimized catalytic reactions. However, only few examples have been transferred to industrial processes (Collins *et al.*, 1992; Hawkins & Watson, 2004; Blaser *et al.*, 2007) in many cases because of the expenses associated to ligand and catalyst loss.

The efficient separation of expensive catalysts and ligands to enable reuse in subsequent cycles is a main challenge that meets both industrial economical needs and new stricter environmental regulations. We have long been interested in the design and the synthesis of new chiral catalysts for exploring new asymmetric catalytic reactions or for improving existing ones (Manoury *et al.*, 2000; Mourgues *et al.*, 2003; Routaboul *et al.*, 2005; Lopez Cortes *et al.*, 2006; Mateus *et al.*, 2006; Routaboul *et al.*, 2007; Le Roux *et al.*, 2007; Labande *et al.*, 2007; Diab *et al.*, 2008). Among the numerous phosphine ligands reported to date, ferrocenyl phosphines functionalized by an oxygen atom (PO ferrocenyl phosphines) constitute a distinct class of hemilabile ligands attracting increasing interest (Breit & Breuniger, 2004; Atkinson *et al.*, 2004; Breit & Breuniger, 2005; Teo *et al.*, 2006; Yu *et al.*, 2007; Mateus *et al.*, 2006). We have recently developed promising PO ferrocenyl ligands (Mateus *et al.*, 2006; Audin *et al.*, 2009). In addition, we recently took interest in improving catalyst recycling using ionic liquid, water or PEG as catalyst "liquid carriers" and in investigating the influence of these media on both the catalytic reaction and the recycling efficiency. To reach this goal, we have prepared a new family of PO ferrocenyl phosphine-ethers, bearing charged (imidazolium) or neutral (monomethylether PEG 750, tetraethylbisphosphonate) polar tags (Audin *et al.*, 2009) to increase their solubility in non conventional media. The simplest member of this new family is compound **2 b** (Scheme 1) which efficiency in the Suzuki-Miyaura reaction has been demonstrated (Yoshida & Itami, 2002).

The title molecule **2a** is built up from a ferrocenyl moiety in which one Cp ring is substituted by a sulfur protected phosphine and a ((4-methylphenyl)-methoxy)methyl group resulting in a planar chirality. As the space group is centrosymmetric the two enantiomers *R/S* are present in the crystal (Fig. 1). There are two molecules with the same configuration within the asymmetric unit. As shown by molecular fitting (Spek, 2009), the two molecules have very closely related geometry (Fig. 2).

The ether chains are roughly planar with the largest deviation being 0.034 (2) Å at C4 and 0.100 (2) Å at O1. These planes makes dihedral angle of 83.21 (13) ° or 88.03 (13) ° for molecule 1 and 2 respectively. The benzyl groups are twisted with respect to these plane by dihedral angle of 49.21 (17) ° and 33.04 (23) ° for molecule 1 and 2 respectively.

The Cp rings within the ferrocene moiety have intermediate conformation between eclipsed and staggered with a twist angle of 16.6 (2) ° and 8.9 (2) ° respectively. These Cp rings are slightly bent with respect to each other making dihedral angles of 2.16 (24) ° and 4.06 (21) ° respectively. The S atom is *endo* with respect to the Cp ring by 0.884 (7) Å and 0.992 (6) Å respectively.

supplementary materials

There are weak intra and intermolecular C—H $\cdots\pi$ interactions involving H atoms of phenyl rings and related phenyl rings either to the same molecule or to a symmetry related one (Table 1, *Cg*1 is the centroid of the C111—C116 ring whereas *Cg*2 is the centroid of the C211—C216 ring).

Experimental

In a Schlenk tube, 0.75 g of the racemic 2-thiodiphenylphosphino(hydroxymethyl)ferrocene (1.74 mmol) was dissolved in 8 ml of dry dichloromethane. A 54% solution of tetrafluoroboric acid in ether (0.73 ml, 5.30 mmol) was then added. After 1 min stirring, a solution of 2.5 g of 4-methylbenzylalcohol (20.5 mmol) in 8 mL of dry dichloromethane was added. After 1 min of stirring, the crude material was filtered on silica gel with ether as eluent. After evaporation of the solvent, 0.4 g of **2a** was obtained as a yellow solid (yield = 43%). ^1H NMR (200.1 MHz, CDCl_3), d (p.p.m.): 7.90–7.65 (4H, m: PPh $_2$); 7.52–7.34 (6H, m: PPh $_2$); 7.05 (2H, d, $J = 7.9$ Hz: Ph); 6.95 (2H, d, $J = 7.9$ Hz: Ph); 4.89 (1H, d, $J = 10.9$ Hz: CpCH $_2$); 4.66 (1H, m: subst Cp); 4.45 (1H, d, $J = 10.9$ Hz: CpCH $_2$); 4.35 (1H, m: subst Cp); 4.33 (5H, s: Cp); 4.29 (2H, d: 2.9 Hz: PhCH $_2$ O); 3.85 (1H, m: subst Cp); 2.33 (3H, m: CH $_3$). ^{13}C NMR (50.3 MHz, CDCl_3), d (p.p.m.): 136.8 (s: quat Ph); 135.4 (s: quat Ph); 134.8 (d, $J_{\text{PC}} = 87.1$ Hz: quat PPh $_2$); 133.6 (d, $J_{\text{PC}} = 86.1$ Hz: quat PPh $_2$); 132.2 (d, $J_{\text{PC}} = 10.7$ Hz: PPh $_2$); 132.1 (d, $J_{\text{PC}} = 10.7$ Hz: PPh $_2$); 131.2 (d, $J_{\text{PC}} = 2.2$ Hz: PPh $_2$); 131.1 (d, $J_{\text{PC}} = 2.2$ Hz: PPh $_2$); 128.8 (s: Ph); 128.1 (d, $J_{\text{PC}} = 12.3$ Hz: PPh $_2$); 128.0 (d, $J_{\text{PC}} = 12.3$ Hz: PPh $_2$); 127.7 (s: Ph); 88.3 (d, $J_{\text{PC}} = 12.1$ Hz: quat Cp); 75.2 (d, $J_{\text{PC}} = 12.5$ Hz: subst Cp); 75.6 (d, $J_{\text{PC}} = 94.7$ Hz: quat Cp); 74.5 (d, $J_{\text{PC}} = 9.4$ Hz: subst Cp); 72.4 (s, PhCH $_2$ O); 70.7 (s: Cp); 69.4 (d, $J_{\text{PC}} = 10.4$ Hz: subst Cp); 66.7 (s: CpCH $_2$ O); 21.3 (s: CH $_3$). ^{31}P NMR (81.0 MHz, CDCl_3), d (p.p.m.): 43.1. Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations

supplementary materials

between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.

Hydrogen-bond geometry (\AA , $^\circ$)

Cg1 and Cg2 are the centroids of the C111–C116 and C211–C216 rings, respectively.

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
C312—H32 \cdots Cg1	0.95	2.82	3.703 (3)	156
C123—H123 \cdots Cg2 ⁱ	0.95	2.91	3.741 (4)	147

Symmetry codes: (i) $x, y+1, z$.
