Received 24 September 2010; accepted 6 October 2010

Key indicators: single-crystal X-ray study;  $T = 130\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.002\text{ \AA}$ ; disorder in solvent or counterion;  $R$  factor = 0.037;  $wR$  factor = 0.114; data-to-parameter ratio = 15.1.

Crystals of the title compound (systematic name: 3 $\beta$ -hydroxy-olean-12-en-28-oic acid ethanol monosolvate),  $C_{30}\text{H}_{48}\text{O}_3 \cdot C_2\text{H}_5\text{OH}$ , were obtained from unsuccessful co-crystallization trials. The asymmetric unit contains two symmetry-independent oleanolic acid molecules, as well as two ethanol solvent molecules. Intermolecular O–H···O hydrogen bonds stabilize the crystal packing. In the oleanolic acid molecules, ring C has a slightly distorted envelope conformation, while rings A, B, D and E adopt chair conformations and rings D and E are *cis*-fused. Both independent ethanol molecules are orientationally disordered [occupancy ratios of 0.742 (8):0.258 (8) and 0.632 (12):0.368 (12)].

## Oleanolic acid ethanol monosolvate

A. Froelich and A. K. Gzella

### Comment

Oleanolic acid is a pentacyclic triterpenoid occurring abundantly in plants as a glycoside or a free compound. Oleanolic acid and some of its derivatives, both natural and semi-synthetic, show interesting biological activity which is the reason for the extensive studies on this class of compounds (Liu, 1995; 2005). There are 135 structures deposited in CSD Database, version 5.31 (Allen, 2002). However, the X-ray analysis of the structure of oleanolic acid has not been undertaken because of the difficulties with obtaining a crystal suitable for the investigations.

The structure presented in this paper was solved for the crystal obtained during the unsuccessful co-crystallization attempts. Crystallization process was carried out using ethanol with the addition of 12 $\alpha$ -bromo-3 $\alpha$ -aza-*A*-homo-18 $\beta$ -olean-28,13 $\beta$ -olide. The impact of the latter one on the crystals size requires further investigations.

Oleanolic acid crystallizes in form of an ethanol solvate. The asymmetric unit contains two symmetry-independent triterpenoid molecules (host) and two ethanol molecules (guest). Both solvent molecules are orientationally disordered. The figure 1 shows that in ethanol molecule A all atoms whereas in molecule B only methylene and methyl groups are split into two alternative positions. In molecule A the non-H atoms assigned to O1AA, C1AA and C2AA positions have the site occupancy factor of 63% whereas in molecule B the carbon atoms assigned to C1BA and C2BA positions have the factor of 74%.

The conformational differences between the symmetry-independent oleanolic acid molecules A and B are significant only in the angular arrangement of the carboxylic group. In molecule A, the carbonyl group C28=O2 adopts conformation halfway between synperiplanar and synclinal (-sp/-sc) with respect to C17—C18 bond [torsional angle C18A—C17A—C28A—O2A: -27.6 (2) $^{\circ}$ ]. In molecule B, the conformation is halfway between anticlinal and antiperiplanar (+ac/+ap)[torsional angle: C18B—C17B—C28B—O2B: 145.84 (16) $^{\circ}$ ]. The angular orientation of the carboxylic group in both independent molecules A and B is stabilized by the intermolecular hydrogen bonds in which this group acts both as a proton donor and acceptor (Fig. 2, Table 1).

In both independent molecules, rings *A*, *B*, *D* and *E* have chair conformation distorted to a different degree. Ring *C* assumes an envelope conformation [Cremer & Pople (1975) parameters molecule A:  $Q = 0.565$  (2)  $\text{\AA}$ ,  $\theta = 51.1$  (2) $^{\circ}$ ,  $\phi = 1.7$  (2) $^{\circ}$ ; molecule B:  $Q = 0.544$  (2)  $\text{\AA}$ ,  $\theta = 50.5$  (2) $^{\circ}$ ,  $\phi = 4.5$  (3) $^{\circ}$ ].

The dihedral angles *A/B*, *B/C*, *C/D* and *D/E* in molecule A are 17.41 (8), 13.75 (10), 14.13 (10) and 57.92 (6) $^{\circ}$ , while in molecule B are 14.68 (10), 12.34 (11), 17.47 (10) and 60.26 (6) $^{\circ}$ . Rings *A/B* and *B/C* are *trans*-, whereas rings *D/E* are *cis*-fused. Each of the axial methyl groups C24, C25 and C26 repulses the adjacent methyls. This results in the lengthening of the interatomic distances C24···C25 and C25···C26 [molecule A: 3.2434 (23) and 3.2648 (23)  $\text{\AA}$ ; molecule B: 3.2645 (25) and 3.1958 (24)  $\text{\AA}$ ] in comparison with the undistorted molecule of 1a,3a-dimethylcyclohexane in which the distance between the methyl carbons is merely 2.52  $\text{\AA}$  [Spirlet *et al.*, 1980]. An additional consequence of the repulsive interactions between the methyl groups is deformation of the angles C4—C5—C10 and C8—C9—C10 to the values of 117.30 (13) and 117.33 (12) $^{\circ}$  (molecule A) and 117.90 (13) and 116.98 (13) $^{\circ}$  (molecule B).

## supplementary materials

---

The hydroxyl group at C3 in molecules A and B of oleanolic acid is equatorial with respect to ring *A* and adopts  $\beta$  orientation.

In the crystal lattice, the symmetry-independent molecules A and B of oleanolic acid are connected with hydrogen bonds O1A-H11 $\cdots$ O2B and O1B-H12 $\cdots$ O2A<sup>i</sup> (Fig. 2, Table 1) into infinite chains extending along the *c* axis. The hydrogen bonds involve the C3 hydroxyl group and the carbonyl oxygen atom of the C17 carboxylic group. Both of the mentioned functional groups form also hydrogen bonds with the solvent molecules. The ethanol molecules marked A are hydrogen bonded (O1AA-H1AO $\cdots$ O1A and O3B-H32 $\cdots$ O1AA) to the triterpenoid molecules A and B belonging to the same chain, whereas the ethanol molecules B are linked through the O3A—H31 $\cdots$ O1BA<sup>ii</sup> and O1BA-H1BO $\cdots$ O1B hydrogen bonds with the triterpenoide molecules A and B but from the adjacent chains (Fig. 2, Table 1). Therefore, the ethanol molecules B connect the chains of triterpenoid molecules into two-dimensional layers that extend parallel to the *bc* plane. The layer thickness is about half of the *a* parameter length.

### Experimental

Oleanolic acid was extracted from mistletoe leaves. Equimolar quantities of oleanolic acid and 12 $\alpha$ -bromo-3 $\alpha$ -aza-*A*-hom-18 $\beta$ -olean-28,13 $\beta$ -olide as an additive were dissolved together in hot ethanol and the mixture was set aside to crystallize at room temperature.

### Refinement

Except for the triterpenoide hydroxyl and carboxylic groups H atoms which were refined freely the remaining H atoms were positioned into the idealized positions and were refined within the riding model approximation: C<sub>methyl</sub>—H = 0.96 Å, C<sub>methylene</sub>—H = 0.97 Å, C<sub>methine</sub>—H = 0.98 Å, C( $sp^2$ )—H = 0.93 Å, O—H = 0.82 Å;  $U_{iso}(\text{H}) = 1.2U_{eq}(\text{C})$  or  $1.5U_{eq}(\text{C})$  for methyl H. The methyl atoms were refined as a rigid group, which was allowed to rotate. 4907 Friedel pairs were used to determine the absolute configuration which is also known by reference to the chirality of the oleanane derivatives.

### Figures

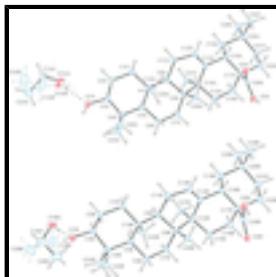

Fig. 1. The independent molecules of oleanolic acid and ethanol showing the atomic labelling scheme. Non-H atoms are drawn as 30% probability displacement ellipsoids and H atoms are drawn as spheres of an arbitrary size.

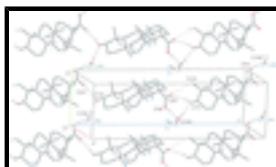

Fig. 2. The hydrogen bonding (dashed and dotted lines) in the title structure. Symmetry codes: (i)  $x, y, -1 + z$ ; (ii)  $x, 1 + y, 1 + z$ . The H atoms not involved in hydrogen bonds have been omitted for clarity.

## Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
